HOMOLOGOUS SERUM JAUNDICE

A Problem in the Operation of Blood Banks

I. HERBERT SCHEINBERG, M.D.
THOMAS D. KINNEY, M.D.
and
CHARLES A. JANEWAY, M.D.
With the assistance of [illegible] V. Taylor and Virginia S. Poole
Boston

Recognition is being given increasingly to the problem of hepatitis following the prophylactic or therapeutic administration of human blood and its products. Recent papers have described the clinical aspects of the disease and have reviewed the literature.[1] As yet, no method of prevention of homologous serum jaundice has been devised, and its relation to infectious hepatitis requires further clarification. The available evidence indicates that the icterogenic agent of both diseases is probably a virus.[1c]

The present paper has two purposes: first, to report cases of homologous serum jaundice which were observed during the year ending August 1945 in the Peter Bent Brigham Hospital in order to emphasize the importance of this disease, and second, to discuss the problem of serum jaundice and possible methods for its prevention in the operation of a hospital blood bank.

METHODS AND MATERIAL

A description of the operation of the blood bank which has been run jointly by the Children's Hospital and the Peter Bent Brigham Hospital will clarify the problems to be discussed. A brief history is taken from each donor, which is designed to exclude those with malaria, syphilis or an acute illness. Examination of the skin, mucous membranes, cardiovascular system and genitalia is supplemented by a hemoglobin determination, a serologic test for syphilis (Hinton) and blood groupings (including Rh factor). Approximately 500 cc. of blood are drawn aseptically into bottles which contain a solution of sodium citrate kept at 5 to 10 C. and used as whole blood, if needed, at any time during the ensuing five to ten days.[2] At the conclusion of this period the red cells are discarded and the plasma from ten to fifteen bottles is combined to make a pool. Each pool is numbered, a sample cultured, and a record made of the donors whose plasma it contains. The pool is then frozen and stored in the frozen state until needed—often for a year or more. When it is to be used, the plasma is thawed at 37 C. and divided into 250 cc. units. Often many weeks elapse between the administration of the first and last unit of a pool, during which time the plasma is kept at 5 to 10 C. The complete record of each pool contains the names of all patients who received plasma from it, as well as notes of any immediate reactions that were reported.

Homologous serum jaundice is a form of acute hepatitis which follows the receipt of human blood, plasma or some of its derivatives after an interval of forty to one hundred and eighty days. Three criteria were used in selecting the cases included in this report. First, each patient had received plasma and/or blood between fifty-four and one hundred and thirty-five days before the onset of jaundice. Second, in each instance the clinical observations were characteristic of acute hepatitis.[1f] Third, in the fatal cases the pathologic findings were those of fatal hepatitis.[3]

These cases were discovered in one of three ways. In some instances patients were admitted to the hospital with hepatitis, and the history of prior receipt of blood or plasma was elicited. Other patients had been in the hospital previously, and hepatitis was found to have developed subsequently by follow-up studies carried out either because of interest in the original disease or because these patients had received plasma suspected of being icterogenic. The third source was the discovery at autopsy of acute hepatic atrophy in a patient who had received plasma or blood.

The cases will be presented in three groups. The first comprises 5 persons whose disease may be traced to the same pool of plasma. In the second and third groups, comprising 3 fatal and 5 nonfatal cases respectively, plasma from a common pool was not a factor.

REPORT OF CASES OF HOMOLOGOUS SERUM JAUNDICE

A. Pool 219

Pool 219 was made of the plasma from blood collected in the spring of 1944. It was kept frozen until early in 1945 when, over the course of several months, it was administered to 9 patients, among whom 3 definite and 2 possible instances of hepatitis developed. Of the remaining 4 patients, 2 died of their original disease before sufficient time had elapsed to permit them to contract serum jaundice.

In 2 patients jaundice did not develop, although they survived their original disease. S. Dil. was a boy aged 21 months who received plasma from pool 219 and other

plasma and blood when he was in the Children's Hospital for treatment of a perforated appendix and generalized peritonitis. B. S. was a woman aged 71 with hypertensive cardiac disease and auricular fibrillation, who was admitted to the surgical service because of an embolus in a branch of the left femoral artery. She received 1 unit of pool 219 plasma during embolectomy. Six months after the discharge of the patient, no symptoms of hepatitis had developed.

The course of these 9 patients is summarized in figure 1, and the case histories of those in whom homologous serum jaundice developed follows:

Definite Cases of Homologous Serum Jaundice

Case 1.—B. H., a woman aged 28, a housewife, was originally admitted in December 1944 because of anuria following a reaction to a blood transfusion given for hemorrhage incident to an abortion. During this admission her liver and spleen were not palpable. For many days she was severely uremic, anemic and edematous, and she was given seven blood transfusions and plasma from nine pools, of which one was pool 219. She recovered and was discharged. Thirteen weeks (eighty-nine to ninety-four days) after receiving the plasma there developed nausea, anorexia, diarrhea and subcostal discomfort, and she entered the hospital for the second time. On physical examination slight icterus and a tender liver, which was barely palpable on deep inspiration, were noted. The leukocyte count was 7,400; the icteric index was 30; the serum bilirubin determination was 4.1 mg. per hundred cubic centimeters, and the prothrombin level was less than 10 per cent of normal. Her condition rapidly became poorer, and the icterus increased; she lapsed into coma and died six days after admission.

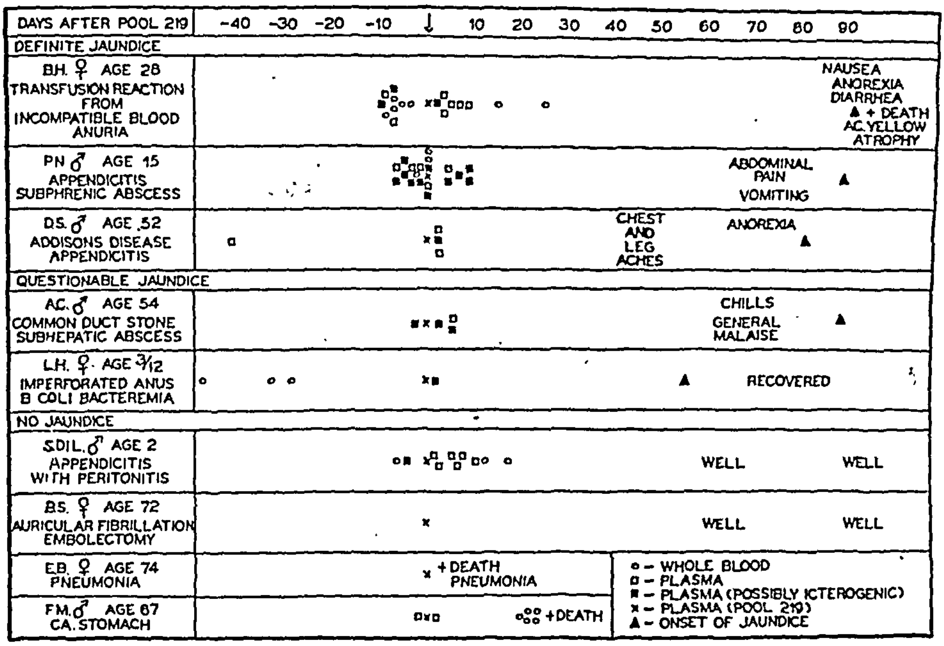

Fig. 1.—Homologous serum jaundice, pool 219.

At autopsy there was pronounced icterus. The liver weighed 1,050 Gm. and was flabby. The surfaces were smooth and a mottled greenish yellow-brown. The appearance of the cut surfaces of the liver was varied. Large areas, particularly in the right lobe, were pale yellow-brown, and the lobular markings were indistinct. In other large areas the sinusoids were bright red and prominent and the parenchyma between the sinusoids was pale yellow. There was no gross evidence of scarring or vascular damage.

Representative sections were fixed in Zenker's fluid and 10 per cent solution of formaldehyde and stained with eosin and methylene blue, Mallory's phosphotungstic acid and Mallory's aniline blue stains. There was complete destruction of the hepatic architecture. All liver cells appeared to be severely damaged, and the great majority were necrotic. The cells as a whole had a shrunken appearance, the boundaries of the cells were hazy or broken, the cytoplasm stained poorly and the nuclear outlines were indistinct. A few liver cells in the vicinity of the portal areas took a deeply basophilic stain. The cytoplasm of these cells was vacuolated and the nuclei pyknotic. No regenerating cells were seen. The biliary ducts were intact. In only an occasional canaliculus was there biliary stasis, and few ducts showed evidence of proliferation. There was moderate polymorphonuclear leukocytic infiltration in the portal and the immediate periportal areas. There was no evidence of repair or proliferation of connective tissue (fig. 2).

The gallbladder was the usual size and shape and contained 10 cc. of thin light brown bile. It was not thickened, and there were no stones. The spleen weighed 385 Gm. It was soft and flabby. Cut surfaces were reddish gray, and the malpighian bodies were prominent. On microscopic examination the splenic pulp was seen to be engorged with red blood cells. A small amount of hemosiderin was found throughout the splenic pulp.[4]

Case 2.—P. N., a schoolboy aged 15 who had catarrhal jaundice five years previously, was admitted to the surgical service on Jan. 11, 1945, with acute appendicitis and peritonitis. A subphrenic abscess and a sterile pleural effusion had developed following operation, and he received three blood transfusions and 17 units of plasma, of which 2 came from pool 219. He recovered completely. Early in April, after abdominal and midback pain and vomiting of one day's duration, he was admitted to the surgical service. Physical examination elicited only tenderness over the lower part of the abdomen. The leukocyte count was 15,800; the icteric index was 9, and the stool was brown. He went home well in two days. Thirteen weeks after receiving the plasma of pool 219 he noted anorexia, fatigue, weakness and mild itching of his hands. These symptoms were followed within three days by a temperature of 102 F. When he was admitted to the medical service April 21, 1945 he was moderately jaundiced; there was tenderness to percussion over his liver, which could not be felt, and a palpable spleen. The leukocyte count was 6,000; the icteric index was 50; the serum bilirubin level was 14.7 mg. per hundred cubic centimeters; the stool was brown and the urine contained bilirubin. He recovered uneventfully. About two weeks prior to the onset of jaundice he had been in the company of a girl who had been discharged from this hospital a month before following an attack of infectious hepatitis.

Case 3.—D. S., a man aged 52, of Italian birth, had Addison's disease. At the end of November 1944 he underwent operative intervention in this hospital for acute appendicitis and received 12 units of plasma. Thereafter he was well until Jan. 12, 1945, at which time he was admitted with an infection of the upper part of the respiratory tract and an addisonian crisis. He was given 5 units of plasma, of which 2 came from pool 219. He recovered rapidly but about six weeks later suffered from "chest and leg pains," which were apparently not severe enough to warrant seeking medical aid. Jaundice appeared in the first week of April, twelve weeks after he had received the plasma from pool 219. On admission on April 9 he was jaundiced, but the liver and spleen were not felt. The leukocyte count was 5,000; the icteric index was 25; the serum bilirubin determination was 5.9 mg. per hundred cubic centimeters; the prothrombin level was normal; the stool was brown, and the urine contained bilirubin. His hospital course and convalescence were uneventful.

---

[4] This case is being reported in full elsewhere by Burwell, E. L.; Kinney, T. D., and Finch, C. A.: Renal Damage Following Intravascular Hemolysis, *New England J. Med.*, to be published.

Questionable Cases

CASE 4.—A. C., an Italian man aged 54 entered the hospital because of three weeks of increasing jaundice. Abdominal exploration was performed, and his pancreas was removed. At this time he received blood and plasma, including 2 units from pool 219. Pathologically, the pancreas showed a well differentiated, slowly growing adenocarcinoma with a decided degree of fibrous stroma. The jaundice of the patient subsided. In May 1945, eighty-five to ninety-two days after the plasma from pool 219 was given, jaundice reappeared. Physical examination revealed normal conditions save for icterus; his leukocyte count was 6,800; his icteric index, 20, and his serum bilirubin, 2.5 mg. per hundred cubic centimeters. Although his jaundice diminished, he soon began to have recurrent episodes characterized by chills, reappearing jaundice and leukocytosis during the next six months. Finally a second laparotomy was carried out, and a stone was found in the common bile duct. Cholangiograms at this time showed moderate dilatation of all the intrahepatic biliary ducts. The jaundice slowly cleared and the stools became brown, although some bile continued to drain from the wound. During the next six months the patient grew progressively sicker, and two subdiaphragmatic abscesses were drained. He was admitted on May 17, 1946 because of weakness, vomiting and a bloody discharge from his abdominal incision. Icterus increased rapidly, and the patient died July 9, 1946.

At autopsy pronounced generalized icterus was present. There was edema of the extremities and over the sacrum. A total of 5,800 cc. of clear amber fluid was found in the peritoneal cavity. All the structures in the right upper quadrant of the abdomen were bound together by dense, firm, white adhesions. An abscess containing light green pus was found between the diaphragm and the right lateral margin of the liver. The liver weighed 960 Gm. The capsule, except where it was involved in adhesions or inflammatory reaction, was smooth and green-brown. The left lateral and anterior edges of the left lobe were firm, white and fibrotic. Occasional small, firm, white tumor nodules were scattered throughout the liver. Sections of the liver were green-brown, and thin, white purulent matter exuded from both large and small biliary ducts. The portal vein just proximal to the splenic vein was decidedly constricted by the dense adhesions in this area. The gallbladder was thickened, surrounded by adhesions and contained pus. The common duct was partially obscured by adhesions, and its opening into the jejunum could not be identified. The head and adjacent body of the pancreas had been removed, as had the first and second portions of the duodenum. The remaining pancreatic tissue showed definite softening and atrophy.

Microscopic sections of the liver disclosed a pronounced increase in fibrous tissue in the portal areas, with decided lymphocytic infiltration. There was an acute cholangitis and pericholangitis with stasis of the bile and some proliferation of the biliary duct. The tumor nodules were made up of well differentiated adenocarcinoma. The gallbladder showed chronic cholecystitis. There was complete disappearance of the acinar tissue of the pancreas, with only a few islets and large ducts present in the scar tissue. Well differentiated adenocarcinoma was found in sections of the scar tissue from the regions near the site of the head of the pancreas.

In the light of the preceding history, the attack of jaundice in May 1945 cannot be definitely diagnosed as homologous serum jaundice, although it is equally impossible to state that the patient did not have this disease at that time. The latter is true because the jaundice appeared between the eighty-fifth and ninety-second day after the administration of the icterogenic plasma and the low white blood cell count and clinical course were consistent with those of homologous serum jaundice. At autopsy the conditions observed in the liver were those that are associated with long-standing biliary obstruction with superimposed infection. However, this would not invalidate the assumption that the patient had had homologous serum jaundice, as little or no residual stigmas are found in the liver after recovery from homologous serum jaundice.

CASE 5.—L. H., a baby girl aged 3½ months, was admitted on Sept. 25, 1944 for repair of a colostomy and intra-abdominal adhesions resulting from an operation for imperforate anus at an outside hospital. She had to have four abdominal operations, including an ileostomy, because of repeated bouts of intestinal obstruction; she received six transfusions of plasma and eleven of blood up to Jan. 31, 1945, at which time she was given 50 cc. of plasma from pool 219 and, on the following day, a like amount from pool 191. Fifty-six days later, on March 27, 1945, jaundice developed and another exploratory operation was performed. Many adhesions were found, which accounted for the symptoms of intestinal obstruction. The gallbladder was somewhat distended, but no definite evidence of biliary obstruction was discovered. Two weeks later her jaundice had disappeared, and the child did well until August 1945, when there developed diarrhea, then bacteremia and meningitis due to Escherichia coli. She died Aug. 25, 1945.

At autopsy the body was that of a normally developed and fairly well nourished white female infant. There were multiple operative scars over the abdomen and extensive fibrous adhesions throughout the peritoneal cavity. An ileostomy and ileo-ileal side to side anastomosis were patent. The proximal two thirds of the small intestine was greatly distended. There was an acute and chronic enteritis. The liver weighed 370 Gm. (normal weight, 304 Gm.) and was of normal size, color and consistency. The cut surfaces showed normal lobular architecture with scattered areas of yellow mottling. Microscopic sections of the liver showed slight lymphocytic infiltration in the portal spaces. There was moderate vacuolization of hepatic cells in the periportal regions. Hemosiderin was found in macrophages in the portal areas and in the Kupffer cells. In places the sinusoids were dilated and the hepatic cell cords narrowed. The gallbladder was completely encased by fibrous tissue, which could be dissected from it with ease, but the gallbladder itself was not abnormal. The biliary ducts were patent and of normal caliber. The spleen was normal. In addition to the preceding observations the patient had an acute focal meningitis due to Aerobacter aerogenes; acute and chronic bronchitis, and pulmonary edema.

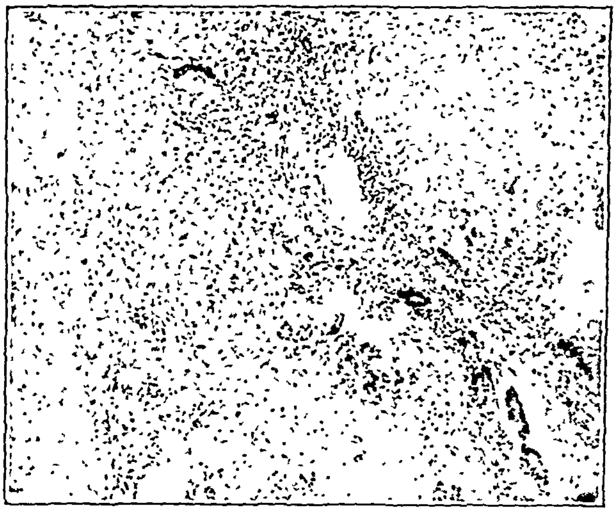

Fig. 2.—Photomicrograph showing extensive hepatic cell damage and loss of structure; eosin and methylene blue stain.

B. Other Fatal Cases

CASE 6.—J. F. L., a man aged 59, was admitted in September 1944 with diabetes mellitus and symptoms of cholelithiasis for twenty years. On admission his liver was palpable 4 fingerbreadths below the costal margin, but the spleen could not be felt. Gallstones were demonstrated roentgenologically, and a cholecystectomy was performed on Oct. 19, 1944; the gallbladder, containing stones, was found to be bound down by adhesions. The intestine protruded after operation; a wound abscess developed at the edge of the liver, and the patient exhibited transient auricular fibrillation. Between October 20 and November 20 he received 20 units of plasma and four transfusions of whole blood. He was discharged improved.

On Jan. 20, 1945 he reentered with anorexia, nausea, vomiting and fever of ten days' duration. The physical observations were unchanged. The leukocyte count was 12,400; the icteric index was 51; the alkaline phosphatase measured 9.4 Bodansky units; the stool was brown with a 2 to 3 plus guaiac reaction, and urinalysis was positive for bilirubin. In the hospital the patient grew steadily worse. The icteric index rose to 100 and the white blood cell count climbed to 24,000, although the stools remained brown and the prothrombin level, normal. Nausea and vomiting were intractable, coma developed and ascites collected, requiring a paracentesis. The jaundice had appeared sixty-one days after the last and ninety-two days after the first of the many plasma infusions of the patient.

At autopsy the body was decidedly icteric. There was a sinus tract from which thin green fluid could be expressed, running from the upper edge of the healed cholecystectomy incision to the site of the gallbladder. The gallbladder had been completely removed, and its place was taken by dense scar tissue. There was 5,500 cc. of clear yellow-green fluid present in the peritoneal cavity.

The liver weighed 2,080 Gm. and was soft and flabby. The external surface was slightly granular and mottled yellow-green. Cross sections of the liver showed large focal areas in which there was pronounced congestion of the inusoids. Here the parenchyma of the liver was green and extremely soft with indistinct lobular markings. Elsewhere the sinusoids were not so prominent and the parenchyma was a homogeneous yellow-green, firm in consistency; the lobules appeared to be divided by a delicate gray network. In still other, but smaller, regions the liver was deep red-blue and soft in consistency, and there was complete loss of structure. The common duct was patent. Microscopic examination showed great destruction of the hepatic parenchyma. Many liver cells had disappeared, and there were either broad areas of hemorrhage or bands of homogeneous young fibrous tissue between the remaining cells. There was diffuse polymorphonuclear leukocytic infiltration. The remaining cells were well outlined, with homogeneous basophilic cytoplasm which showed only occasional vacuolization. The nuclei were round and regular with distinct chromatin networks, though occasional cells contained several nuclei, suggesting regeneration. Single, homogeneous, round, deeply acidophilic bodies, of the size of liver cells, were seen. Pigment-laden Kupffer cells were prominent. There was no evidence of dilatation of the biliary ducts or of biliary stasis. Proliferation of the biliary ducts was well defined throughout the scarred areas. The findings in the liver were not considered to be compatible with changes resulting from disease of the gallbladder or obstruction of the common duct but were considered to be consistent with the lesions found in homologous serum jaundice. The spleen weighed 200 Gm., was soft and flabby and dull red-gray. Microscopic examination showed decided congestion of the pulp with red blood cells.

Case 7.—J. P. M., a man aged 55, was admitted in June 1944 because of hemorrhage from a duodenal ulcer of eighteen years' duration. On physical examination, a sharp nontender hepatic edge was felt 2 fingerbreadths below the costal margin. The prothrombin level was normal, but there was 30 per cent sulfobromophthalein sodium retention in thirty minutes with an initial dose of 5.7 mg. per kilogram of body weight. Eight days later a subtotal gastrectomy was performed. At operation the "liver appeared free from disease and the gallbladder appeared normal," according to the surgeon. Between June 27 and July 26, 1944 the patient received 6 units of plasma and 2,500 cc. of whole blood. He was discharged August 5, but on Sept. 2 he was readmitted because of three days of postprandial diffuse abdominal pain, together with vomiting and obstipation. The temperature was 101.5 F.; the pulse rate was 90; there was slight icterus and a tense abdomen. The leukocyte count was 9,000; the icteric index was 10; the stool was black, and the prothrombin time was 70 seconds with a control of 55 seconds. He was febrile and his jaundice deepened during the thirteen days that he remained alive. The leukocyte count was low until the fourth day (6,200) and rose to 25,000 four days before death. The stools became tan and then gray with a 4 plus guaiac reaction, and there was bilirubinuria. Massive ascites appeared, and fluid obtained by paracentesis a week before death had a specific gravity of 1.012 and was sterile to culture. Jaundice had appeared thirty-eight days after the last and sixty-six days after the first infusion of plasma.

At autopsy the body was decidedly icteric. There was 1,000 cc. of pale yellow fluid in the peritoneal cavity. The liver weighed 1,340 Gm. and was soft, flabby and pale yellow. Cross sections were homogeneously yellow, and the usual lobular markings were absent. Microscopic sections, prepared as described previously, showed complete loss of hepatic structure. Almost all the liver cells were necrotic. There was extensive diffuse polymorphonuclear leukocytic infiltration. An occasional small island of liver cells which appeared to be regenerating was found. Round acidophilic bodies, similar to those seen in the cast of J. F. L. (case 6) were found in the areas of greatest destruction. There was active proliferation of the biliary ducts. A few fibroblasts were present, but there was no increase in scar tissue. The gallbladder and extrahepatic ducts were not remarkable. The spleen weighed 100 Gm., and appeared normal on gross and histologic examination.

Case 8.—C. H., a woman aged 68, was admitted on May 2, 1945 because of acute intestinal obstruction. She had noticed rectal bleeding for two years, and for three weeks before admission she had complained of crampy abdominal pain. On physical examination there was tenderness in the left lower quadrant of the abdomen, and a mass was felt on rectal examination. The spleen and liver could not be palpated. At laparotomy, performed May 7, acute intestinal obstruction together with reduplication and diverticulitis of the sigmoid was found. The "liver looked not . . . abnormal" to the surgeon. A transverse colostomy was made; a month later a partial left colectomy was performed, and on July 5 the colostomy was closed. At that time the liver and gallbladder again appeared normal. The patient received plasma on May 5, 6, 7 and 10 and 500 cc. of whole blood on June 7. There was an uneventful convalescence, and the patient returned home.

Suddenly, on July 31, there was pain in the right upper quadrant of the abdomen and fibrillary twitching of the face and extremities appeared. The liver was not palpable. Twelve hours later light icterus was seen, and forty-eight hours after the onset the patient produced coffee-ground vomitus. By August 2 the icteric index was 190 and she was unconscious; on August 4 she died. Jaundice had appeared eighty-three days after the last infusion of plasma, eighty-eight days after the first and fifty-five days after her only whole blood transfusion.

The autopsy was performed at another hospital. The liver weighed approximately 650 Gm., was decidedly shrunken with a wrinkled capsule, and was soft, flabby and mottled yellow and red. A histologic section examined in this hospital showed changes similar to those described in the previous cases, complete destruction of liver cells with diffuse leukocytic infiltration. The biliary ducts were intact, and in a few regions there was evidence of proliferation. There were no other significant observations.

C. Other Nonfatal Cases

Case 9.—A. F., a man aged 49 years, received 1 unit of plasma in July 1944 while undergoing prostatectomy for benign prostatic hyperplasia. After discharge he suffered from vague abdominal complaints. Ten weeks after the administration of the plasma he passed darkly colored urine, and several days later jaundice and symptoms of hepatitis appeared. On readmission his liver was palpable. The icteric index reached 119 with a simultaneous prothrombin level of less than 30 per cent. Thereafter the jaundice gradually diminished, and the icteric index was 19 seven weeks after the onset of the illness.

CASE 10.—J. F. M., a man aged 57, suffered severe and continued intestinal hemorrhage during an attack of typhoid fever treated in this hospital in July and August of 1944. Twenty-one transfusions of whole blood (11 liters) and 2 units of plasma were given in a period of ten days. He recovered, and when seen four and a half months later in the follow-up clinic related that about seven weeks after the transfusions he had had hives for several days, and that two to three weeks later he noted jaundice, fatigue, anorexia, nausea and vomiting, dark urine and putty-colored stools. He improved without medical care but felt tired for a month. In the follow-up clinic, two months after this illness, his liver was palpable 2 fingerbreadths below the costal margin, but this had also been noted when he had typhoid fever. The icteric index was 11, and a sulfobromophthalein sodium test (5 mg. per kilogram of body weight) showed no retention of the dye in his serum after thirty-five minutes.

CASE 11.—J. H., a man aged 28, suffered from both Addison's disease and diabetes mellitus and had been admitted to this hospital about once a month for over two years. On Oct. 8 and 9, 1944 he received 550 cc. of plasma incident to a tooth extraction. He was admitted three times during November and December for treatment of his primary diseases and required plasma (3 units) on December 27 and 28. About Feb. 7, 1945 he passed dark urine; two weeks later nausea, vomiting, anorexia and jaundice appeared; he was readmitted February 27. On physical examination a smooth and nontender liver was felt 2 fingerbreadths below the costal margin, an observation not previously noted, but his spleen was not palpable. On February 28 the leukocyte count, normally low in this patient, was 4,550, with 33 per cent polymorphonuclear leukocytes and 54 per cent lymphocytes. The icteric index was 40; the stool was brown, and the sulfobromophthalein excretion curve showed abnormally high retention. By April 12 the icteric index had fallen to 15, with a leukocyte count of 7,200 and an almost normal sulfobromophthalein sodium excretion curve. From the date of administration of plasma in October to the onset of jaundice, one hundred and thirty-four or one hundred and thirty-five days had elapsed; from the time plasma had been given to him in December until the appearance of jaundice there had been an interval of fifty-four or fifty-five days.

CASE 12.—C. S., a woman aged 67, was admitted May 8, 1945 because of rectal bleeding. On physical examination the liver was just palpable, and a hard mass was felt protruding into the rectal canal. On May 22 a combined abdominal-perineal resection was carried out for carcinoma of the rectum, and that day she received 250 cc. of plasma and 3 units of whole blood. Only slight nausea and anorexia followed the operation, but at the end of June vomiting became severe; between June 28 and July 8 she required 10 units of plasma. Because the vomiting continued until mid-July, a gastrointestinal series of roentgenograms was made, which demonstrated a duodenal ulcer with pyloric obstruction. On July 21, sixty days after the first infusions of plasma but less than twenty-three days after the last, she appeared jaundiced and the icteric index was 47. By July 28 it was 66; the leukocyte count was 5,100, the serum bilirubin, 12.8 mg. per hundred cubic centimeters, and the alkaline phosphatase, 14.5 Bodansky units. Thereafter the patient gradually improved.

CASE 13.—J. D., a man aged 38, was admitted to the surgical service May 19, 1945 because of epigastric pain, nausea and vomiting of five hours' duration. His leukocyte count was 29,000. At laparotomy he was found to have a malrotated cecum with a perforated retrohepatic appendix, although the liver itself appeared normal. During convalescence dehiscence of the wound occurred and he was extremely ill, requiring 10 units of plasma between May 20 and 25. He was discharged June 15. About July 20 he noted anorexia, nausea and headache, and in the following five days dark urine, clay-colored stools and jaundice appeared. When admitted to the medical service August 1, no history of alcoholism, prior hepatic symptomatology or exposure to hepatitis could be elicited. On physical examination, tenderness under the right costal margin was found and neither liver nor spleen was palpated. The temperature was normal; the leukocyte count was 10,000, and the icteric index 78, with a serum bilirubin of 19.1 mg. per hundred cubic centimeters. Tenderness of the right upper quadrant of the abdomen continued for a week; the jaundice became more pronounced, and the patient suffered from transient itching. The liver was never felt. The incubation period from the receipt of plasma to the onset of jaundice was sixty-four to sixty-nine days.

COMMENT

A. Criteria and Cases

There is no confirmatory diagnostic aid which will differentiate homologous serum jaundice from infectious hepatitis. The criteria by which these cases were selected suggest that the former diagnosis was correct but do not prove that the disease was not infectious hepatitis. Moreover, the majority of these patients were over 30 years of age, whereas infectious hepatitis usually occurs in younger persons.

The cases related to pool 219 have the greatest likelihood of being homologous serum jaundice. In 3 of the 7 recipients who lived long enough to have icterus develop it did so, while jaundice, which could have been due either to hepatitis or to obstruction of the biliary ducts, occurred in 2 of the other 4 patients two to three months after receiving the plasma. The incubation period between transfusion and the onset of icterus was remarkably constant, eighty-four to ninety-four days, and is consistent with that given in other reports.[5] While it is true that the recipients in whom jaundice developed had also received blood and/or plasma in addition to that from pool 219, it is in relation to the date on which the plasma from the latter pool was given that the constancy of the incubation period is found. This fact is particularly apparent in case 3; D. S. had received plasma from other pools seven weeks prior to the administration of that from pool 219. Two of the 3 patients had brief periods of illness before the onset of jaundice, which is characteristic of many serum jaundice cases.[6] Finally, P. N.'s history (case 2) of prior "catarrhal jaundice" suggested that his present disease was homologous serum jaundice, for second attacks of infectious hepatitis (catarrhal jaundice) are uncommon,[1b] and an attack of this disease probably does not confer immunity to homologous serum jaundice.[7]

B. Source of Icterogenic Agent

Among donors to an icterogenic plasma pool, at least 1 might be expected to have had a history of jaundice. In investigating the cases of jaundice in the United States Army which followed immunization with yellow fever vaccine made with human serum, Sawyer and his associates[8] concluded that all "highly icterogenic" lots (lots associated with more than 10 cases of jaundice per 1,000 doses net issue) contained some serum from persons with a history of jaundice. After the readmission of patients with jaundice related to pool 219, the 15 donors to this pool were investigated more closely than had been done at the time their blood was taken. All were contacted in person or by mail and were asked if they recalled ever having had jaundice or any illness in the past three years. Specific inquiry with reference to other symptoms of infectious hepatitis was made. They were asked if they had ever received blood or plasma transfusions, or injections of serums or vaccines, and a family and contact history with respect to jaundice was secured.

Twelve of the 15 donors gave completely negative responses to these inquiries. Of the remaining 3, 1 woman aged 29 had had repeated episodes of jaundice throughout her life until her spleen was removed in 1939; pathologic examination of the spleen had confirmed the clinical diagnosis of congenital hemolytic icterus. The second, a man aged 33, was in the Merchant Marine at the time the investigation was carried out, but it was learned from his wife that he had had one brief episode of jaundice three years before he gave his blood. The third man, 30 years of age, was a Navy student at Harvard University at the time of his donation. He had received yellow fever vaccine (lot 1229) in December 1943, but this lot was prepared without human serum. More important, in May 1944, a few weeks after his donation of blood, he reported "loss of appetite, nausea, soreness in the right thoracic region, just at the last rib, yellow stools, easy fatigability and nervousness." He did not recall any jaundice. At that time a roentgen examination of his gallbladder was made at a naval hospital and was reported to have revealed normal conditions. He added that at "the present time (March 1946) I occasionally have similar reactions, especially the soreness and nausea." These symptoms are strongly suggestive of hepatitis, for this can occur without jaundice.[9] Either of these last 2 donors may have been the source of the icterogenic agent of pool 219.

* Suspicious because jaundice developed in more than 1 patient who received plasma from these pools.

C. Incidence and Mortality

Incidence: *If three months is assumed to be the average incubation period of homologous serum jaundice, the 11 patients whose cases are presented in this report received their infectious plasma or blood between June 1944 and May 1945. In this period of a year, 1,494 units of blood and 949 units of plasma were given to patients in the hospital, and a minimum estimate of* the incidence of the disease would therefore be 1 in every 222 transfusions. For the true incidence it would be necessary to follow up all recipients. Case 10, that of J. F. M., shows that some attacks of homologous serum jaundice are so mild that medical assistance is not sought and only follow-up studies will uncover them. This is a huge task. It is probable that as a result of the pooling procedure plasma is much more apt to produce jaundice than is whole blood; the minimum incidence would be 1 in every 86 transfusions of plasma if all these cases resulted from plasma.

That this is actually so is strongly suggested by recent reports from Britain,[10] in which the incidence of jaundice within five months of transfusion was nil in 891 patients who received whole blood and 7.3 per cent in 1,054 patients who received serum or plasma. This higher incidence of the disease in England probably is the result of two factors: first, the larger number of bleedings (from 120 to 800) per pool; and second, the careful follow-up of every recipient. The comparative frequency of icterogenic donors in Britain and the United States as well as the comparative susceptibility of the recipients also may be quite different. These authors were presumably dealing with liquid plasma and serum, whereas the plasma we use has been kept in the frozen state until shortly before its administration.

As a consequence of pooling, even in those instances where a patient who is known to have hepatitis is a recipient of a particular pool and serves as the starting point, the epidemiologic problem is complex. If 1 recipient of a pool contracts jaundice, the determination of the incidence and source of infection in that pool requires the investigation of all the other recipients and all the donors—about 12 of each in our blood bank. A further complication is that most patients who receive plasma require multiple transfusions of plasma and often of blood, thus implicating more than one pool; 10 of the 11 patients here reported received multiple transfusions. Thus, to complete the study of a patient with homologous serum jaundice who has been given plasma from four pools would necessitate contacting roughly 40 to 50 donors and 40 to 50 recipients. Table 1 illustrates this complexity.

What is the risk of homologous serum jaundice to a patient given plasma? The answer to this important question cannot be given at present but should depend on the number of pools from which the patient receives plasma, the number of donors contributing to each pool and the incidence of infectious donors in the community. Sawyer and his colleagues[8] found that 23 of 367 donors gave a history of jaundice and suggested that as high as 6 per cent of the population might be periodic carriers. Lots of homologous blood products which are definitely icterogenic vary greatly in the incidence of jaundice following their administration. Fox and his collaborators[11] proposed that a second etiologic factor must be present in addition to the primary agent in the blood product. They suggested that this second factor might be another infectious agent, chronic intoxication of the liver or lowered hepatic resistance of an alimentary nature. In table 2 are given the diseases which antedated the receipt of the presumably icterogenic plasma and which might have caused hepatic damage in the patients considered in this report and in those recipients of pool 219 who escaped subsequent hepatitis. Most of the patients who contracted jaundice suffered from serious intra-abdominal disease or conditions like Addison's disease or typhoid fever, in which nutrition is affected.

That serum jaundice, like most other infectious diseases, is milder in children is also suggested by the fact that none of our cases except the questionable instance of S. Dil., who received plasma from pool 219, have been recognized in the Children's Hospital, where a considerable amount of the plasma has been used.

Mortality: The mortality in homologous serum jaundice is variable. It has been reported as about 0.2 per cent.[12] in the Army during the outbreak from yellow fever vaccine, as 2 per cent [11] in a Brazilian outbreak with similar vaccine and as 22 per cent in a group of infections following the use of measles serum in England.[1a] In our series the mortality of 36 per cent is abnormally high, since the true incidence of the disease, as just pointed out, is higher than that reported here because only the severer cases came to our attention in the hospital. The number of fatal cases included is high because observations at autopsy served as a source of cases.

D. Methods of Control

Measures designed to prevent homologous serum jaundice may be divided into two categories. The first, with the advantage of immediate applicability, are concerned with the operation of the hospital blood bank and may be expected to diminish the incidence of the disease but not to abolish it. The second comprise possible methods of future control.

1. Methods of Immediate Applicability: In the operation of the blood bank greater efforts should be made to detect the infectious donors; the practice of pooling plasma should be curtailed, and lots of plasma should be given to as few recipients as possible. It is doubtful whether all infectious donors can be found until more is known of the disease itself. However, the examination of donors should include procedures which will uncover the following types of persons, whose blood in our opinion should not be used.

History: any person who has (1) ever had jaundice or hepatitis; (2) had contact with a person with jaundice in the past year;[13] (3) received human blood or its derivatives prophylactically or therapeutically in the past year,[13] except products of plasma fractionation, or (4) been a hospital patient in the past year.[14]

Physical examination: any person who has (1) fever, (2) icterus, or (3) an enlarged or tender liver, or enlarged spleen.

Laboratory examination: any person who has bilirubinuria or hyperbilirubinemia.

Such procedures will detect some nonicteric instances of hepatitis. Neefe, Stokes and their associates [6] closely observed 9 volunteers who had been given inoculations of infective serum and uncovered clinical and laboratory evidence of hepatic dysfunction before jaundice appeared. Of a number of laboratory tests used, they found the detection of bilirubinuria and the retention of sulfobromophthalein sodium the most reliable. Simple tests for bilirubinuria have recently been described, which are of value in detecting infectious hepatitis as early as six days prior to jaundice.[15]

The present procedure at the blood bank at the Peter Bent Brigham Hospital is to determine the serum bilirubin level of any unit of plasma which appears yellow and to discard those units in which the serum bilirubin level is elevated. The fact that blood is infectious for a number of weeks before jaundice develops raises the possibility of holding plasma two or three months and checking donors before using it. A sterile sample of the plasma of each donor whose blood or plasma is used in the bank might be retained for at least a year after his blood or plasma has been administered, in the hope that study of samples from donors of icterogenic blood might lead to better methods for their detection. (Such procedures are worthy of study but not applicable as a routine.)

TABLE 2.—*Possible Sources of Hepatic Damage Prior to Receipt of Plasma or Blood*

Summary of the factors which might have caused hepatic injury in those patients who later contracted hepatitis probably due to plasma or blood. (Also included are those recipients of plasma from pool 219 who survived without contracting hepatitis.)

Case	Recipients of Plasma from Pool 219	Incubation Period, Days
1. B. H.	Pregnancy; abortion; transfusion reaction	89 to 94
2. P. N.	Peritonitis; subphrenic abscess; "catarrhal jaundice" 5 yrs. before	91
3. D. S.	Addison's disease	84
4. A. C.	Jaundice; ? cholelithiasis..........	86 to 93 (questionable jaundice)
5. L. H.	Chronic recurrent intestinal obstruction	56 (questionable jaundice)
S. Dil.	Peritonitis	Jaundice did not develop
B. S.	None: hypertensive cardiovascular disease	Jaundice did not develop
	Recipients of Plasma from Other Pools	
6. J. L.	Cholelithiasis; recurrent jaundice; diabetes mellitus; abscess at edge of liver after cholecystectomy; liver palpable	61 to 92
7. J. P. M.	Peptic ulcer with hemorrhage; palpable liver; 30 per cent sulfobromophthalein retention	38 to 66
8. C. H.	Diverticulitis; reduplication and obstruction of sigmoid	83 to 83
9. A. F.	None: benign prostatic hyperplasia	About 70
10. J. F. M.	Typhoid fever; palpable liver.....	About 65 to 70
11. J. H.	*Addison's disease; diabetes mellitus*	*54 to 55 or 134 to 135*
12. C. S.	Rectal carcinoma; pyloric obstruction; duodenal ulcer	60
13. J. D.	Retrohepatic appendicitis; perforated appendix	64 to 69

The basis for condemning the practice of pooling plasma is the fact that the amount of infective serum necessary to produce the disease is incredibly small. It has even been suggested that small amounts may be more effective in producing the disease than large volumes.[1a] The findings of Sawyer and his associates [8] indicated that an amount of icterogenic serum of the order of 0.01 to 0.001 cc. is all that is needed to transmit hepatitis. Therefore, if each donor's contribution to a pool is 250 cc. (250,000 infective doses if 0.001 cc. is the minimum effective dose) increasing the size of pools should increase the incidence of jaundice. Hence, pools should be kept as small as possible. If pooling is completely eliminated and plasma from 1 donor is administered to only 1 recipient, then an infective donor can cause, at most, 1 case of homologous serum jaundice. The elimination of pooling would necessitate radical changes in the operation of blood banks, one of which would be the requirement that plasma should be typed and cross matched, or treated with group-specific substances.[16] The allocation of a particular pool to a particular patient until there is no chance of his needing more plasma would cut down on the multiple chances for infection resulting from the present random system of distribution.

J., and Hawkinson, V.: Semiquantitative Estimation of Bilirubin in the Urine by Means of the Barium-Strep Modification of Harrison's Test, J. Lab. & Clin. Med. **31**: 914-915, 1946.

2. *Methods of Future Control*: Possible methods of prevention of homologous serum jaundice in the future may be sought along two lines: treatment of the blood or blood product or treatment of the recipient.

The infective principle is extremely rugged. It resists storage in the frozen and dried state, filtration, a temperature of 56 C. for one hour, exposure for months in mediums containing 0.5 per cent each of phenol and ether or 0.2 per cent tricresol and ether extraction.[17] Oliphant and Hollaender have found that the exposure of icterogenic serum in a specially constructed apparatus to ultraviolet light of 2,537 Å may reduce the icterogenic capacity of the serum decidedly.[18] The products of plasma fractionation [19] do not seem to transmit the icterogenic agent.[20] Since these fractions are specific and superior agents for many purposes for which human plasma and serum are employed, their use instead of the latter might be the most effective preventive. Moreover, the use of whole blood should be encouraged for the treatment of traumatic shock, since it is not only probably safer than plasma from the point of view of homologous serum jaundice but also a more physiologic and effective replacement fluid.

Attempts have been made to reduce the incidence of homologous serum jaundice by the intramuscular administration of the gamma globulin fraction of human plasma [21] to the recipients of blood or plasma. The evidence gathered to date [22] does not show conclusively that such treatment is as effective as in infectious hepatitis, but further studies are needed.

CONCLUSIONS

1. Homologous serum jaundice is a disease which must be seriously considered in the operation of a hospital blood bank and in the use of pooled human plasma from any source. In the Peter Bent Brigham and Children's hospitals, over a one year period a minimum estimate is that approximately one in every two hundred plasma or blood transfusions was followed by the disease. If, as is more likely, almost all the infections were the result of the transfusion of pooled plasma, preserved in the frozen state, the minimum incidence was one in every eighty-six plasma transfusions. The criteria for selecting our cases have been presented. Four of these cases were fatal, representing an unexpected late sequel of an original illness from which the patient had apparently recovered.

2. Two methods of control may be immediately instituted in the operation of a blood bank: (1) better detection of possible infective donors by history and physical and laboratory examination, and (2) elimination of the practice of pooling plasma or reduction of the size of pools to a minimum, with limitation of the number of recipients of plasma from each pool as far as possible.

3. Methods of control which may be of value in the future are: (1) the ultraviolet irradiation of plasma or serum; (2) the use of whole blood and the products of plasma fractionation rather than plasma, and (3) the administration of gamma globulin to recipients of plasma or blood.

SUMMARY

1. Eleven cases of hepatitis which was probably due to the prior infusion of human plasma or blood were observed in the course of a year in which 2,443 transfusions of blood and plasma were given.

2. Methods for control of this disease in civilian hospitals include better detection of infectious donors, reduction in the size of plasma pools and elimination of the practice of administering a particular pool to mutiple recipients. The use of whole blood and plasma fractionation products in preference to pooled plasma should be encouraged.

ENDOCRINE THERAPY IN CARCINOMA OF THE PROSTATE

Preparation of Patients for Radical Perineal Prostatectomy

J. A. CAMPBELL COLSTON, M.D.
and
HERBERT BRENDLER, M.D.
Baltimore

As soon as the efficacy of the endocrine management of carcinoma of the prostate, whether by orchiectomy, the administration of estrogens or a combination of the two had been established by numerous observers, chiefly through the fundamental investigations of Herbst [1] and of Huggins,[2] carefully compiled studies soon became available concerning the extent of regression of the primary neoplasm and its metastases following the various types of therapy. From extensive reviews of statistics to date, as well as from experience gained in treating 200 patients with prostatic cancer at the Brady Urological Institute by the administration of diethylstilbestrol, we have come to expect objective regression of the primary growth in approximately 75 per cent of the cases and of its metastases in approximately 45 per cent.

In our clinic we have found it advantageous to classify cases of prostatic carcinoma into four main groups:

I. Early, in which the malignant process is confined to the gland itself and is therefore admirably suited for radical extirpation.

II. Moderately advanced, in which the growth has spread into the bases of the seminal vesicles, into the apex of the gland, or both.

From the James Buchanan Brady Urological Institute, Johns Hopkins Hospital, Baltimore.

Read before the annual meeting of the American Association of Genito-Urinary Surgeons, Stockbridge, Mass., June 22, 1946.

[2] Huggins, C.: Summary of Endocrine Effects in Advanced Prostatic Cancer, New York State J. Med. **43**: 519-521 (March 15) 1943; Treatment of Cancer of the *Prostate*.[3]

III. Advanced, in which, on initial examination, there exists obvious extension throughout the region of the seminal vesicles, inferolateral ligaments and membranous urethra and with fixation of the outer layers of the rectum.

IV. Metastatic: metastases may occur in all three of the aforementioned groups but are, of course, most commonly seen in group III.

During the past three years we have encountered a number of cases in group II which have responded so satisfactorily to diethylstilbestrol therapy that radical surgery subsequently has been undertaken in order to afford these patients the chance of a complete cure. It is with the management of these cases, which may properly be classified as moderately advanced, that this paper is primarily concerned.

THE ACTION OF DIETHYLSTILBESTROL

The mode of action of the endocrines in prostatic cancer is not yet completely understood, nor has the question of diethylstilbestrol therapy versus castration been settled. It is apparent, however, that the actively growing malignant cells require androgen for their viability, and when it is denied them, as after orchiectomy or when it is neutralized, as seems to occur after the administration of diethylstilbestrol, these cells undergo certain changes which can be demonstrated histologically and chemically. As Huggins[3] has stated, "androgen control seriously disturbs the enzyme mosaic of the cancer cells, at least with respect to the important energy-producing protein-catalysts, the phosphatases. As a contribution to the general problem of cancer treatment, it is well to emphasize that any interference with an important enzyme system of a cell, normal or malignant, will cause in that cell a decrease of size and function."

The cytologic changes in the cancer cells following diethylstilbestrol therapy have been intensively studied by Kahle and others.[4] These observers were able to demonstrate definite regressive changes in the nuclear and cytoplasmic material. These changes consist at first of pyknosis of the nuclei and vacuolization of the cytoplasm. Later there occur progressive fragmentation and disappearance of nuclear material, rupture of cell membranes, loss of cellular outline and finally replacement by fibrous stroma, smooth muscle and round cells.

The fact that recrudescence usually occurs after varying lengths of time has been adduced by most observers as evidence that the cancer cells are not actually destroyed but simply remain dormant until becoming reactivated.[5] However, it is common clinically to note that, despite extensive and progressing metastatic manifestations elsewhere during the administration of diethylstilbestrol, the prostate itself remains soft, even atrophic, and in many instances the diagnosis of carcinoma cannot be made by subsequent rectal palpation. Moreover, from a histologic standpoint, as shown by Kahle and others, it would seem that actual cell death had occurred following diethylstilbestrol therapy.[4]

Clinically, after the administration of estrogens one notes in about 75 per cent of the cases a generalized softening of the primary neoplasm associated with a shrinkage in size. These changes are variable, and this variability may be related to the histologic pattern of the tumor, as has been suggested by some, or to the total dosage of estrogen employed. In those patients in whom the carcinoma by rectal palpation is classified as moderately advanced (group II), we have gained the impression from serial examinations during diethylstilbestrol treatment that the earliest signs of regression appear in the periphery of the growth. This has led to the supposition that possibly the marginal cells are more actively growing and therefore show the effects of androgen deprivation more acutely than do those located nearer the center.

Whatever the explanation, the clinical observation has been that, under the influence of diethylstilbestrol, the cancerous process first seems to recede out of the bases of the seminal vesicles and apex of the prostate. This observation has been responsible for our feeling that patients with what has hitherto been considered inoperable prostatic cancer can be given the possible opportunity of cure by radical surgical excision following adequate estrogenic preparation.

THE RADICAL OPERATION

From the insidious nature of the growth of carcinoma of the prostate, it is obvious that early diagnosis is extremely difficult and, in the majority of cases, when the diagnosis is first made the primary neoplasm has extended beyond the capsule into the contiguous structures. The actual percentage of cases deemed suitable for radical surgical removal varies in different clinics. Prince and Vest[6] performed the operation on 9 per cent of patients with prostatic cancer examined at the University of Virginia in a period of two years. In an earlier study[7] it was found that 22.7 per cent of all patients admitted to the Brady Urological Institute between 1937 and 1942 with a diagnosis of carcinoma of the prostate were subjected to radical surgery. The latter percentage is higher than ordinarily would be expected because numerous patients in whom a diagnosis of early carcinoma had been made elsewhere were referred to this clinic in the hope that they could be cured by the radical operation. However small the actual figure, it must be borne in mind that those patients who fulfil the conditions for radical extirpation must not be denied the chance of cure by this method.

It is well to review the clinical criteria for radical surgery in carcinoma of the prostate:

1. On rectal palpation the growth must not extend beyond the capsule into the bases of the seminal vesicles or the region of the membranous urethra. The gland must be freely movable, since fixation indicates spread into the periprostatic tissues.

2. No demonstrable metastases must be present. Acid phosphatase estimates are helpful in many cases but often may remain at normal levels in the presence of extensive metastatic lesions.

3. The patient must be a good surgical risk, and his life expectancy should be reasonable. It is doubtful whether patients in the eighth or ninth decades should

be submitted to the operation, especially in view of the essentially slow growing characteristics of the tumor in these older persons.

RESULTS

The postoperative results of the radical operation at the Brady Urological Institute have been reviewed in detail in earlier publications.[8] It has been pointed out that the operative mortality ranges between 5 and 6 per cent, a figure which compares very favorably with the results of surgery performed for the cure of cancer elsewhere in the body. In the last series of cases reported there occurred 4 hospital deaths in a total of 73 radical prostatectomies done from 1937 to 1942, a mortality percentage of 5.5. Since 1942 there has been only 1 death directly attributable to operation. There are several reasons for the progressive reduction in mortality since 1904, when Young performed the first radical perineal prostatectomy for cancer. These include better methods of hemostasis, including the liberal use of blood transfusions, as well as chemotherapy and the antibiotics. The use of spinal anesthesia has provided better relaxation of the perineal musculature, thus materially improving the technic and shortening the duration of the operation.

THE PREOPERATIVE ADMINISTRATION OF DIETHYLSTILBESTROL

The preparation of patients for radical perineal prostatectomy by the use of diethylstilbestrol has been recommended before,[9] and Vallett[10] has reported a case in which the radical operation was successfully performed after castration.[10] Hitherto, however, no reports have appeared in the literature where a series of cases so managed has been carefully followed and studied from that standpoint. At the Brady Urological Institute 200 cases of cancer of the prostate have been treated with diethylstilbestrol, in all of which the ary neoplasm was considered too extensive on examination to justify radical extirpation. The ses reported here were classified as moderately advanced on rectal examination. All were then maintained on diethylstilbestrol therapy for varying periods, during which time serial rectal examinations were performed. The response of each of these patients to the administration of estrogen was so gratifying that it was deemed worth while to perform the radical operation in order to attempt a complete eradication of the disease. In several other patients similar regression occurred, but their general physical condition and life expectancy contraindicated extensive radical procedures.

In the 7 patients submitted to radical prostatectomy, the preoperative dosage of diethylstilbestrol was 1 to 2 mg. per day. No essential difference in the rapidity or degree of regression of the primary neoplasm has been noted with larger doses. The use of diethylstilbestrol in the dosage recommended has not been attended by untoward symptoms, save for slight swelling and tenderness of the nipples, and, as the growth has receded very satisfactorily on this dosage, larger amounts have not been employed.

REPORT OF CASES

Case 1.—J. E. A., a white man aged 68, first examined Nov. 9, 1943, presented increased urinary difficulty, moderate frequency and nocturia one to four times of one year's duration. He gave no history of back or perineal pain or apparent weight loss. He had been examined elsewhere six weeks previously, at which time a small, hard, oval nodule had been discovered in the right lobe of the prostate. He had therefore been referred here for possible radical perineal prostatectomy.

Physical examination revealed that the patient was in good condition. The penis showed moderately advanced induration of the corpora cavernosa (Peyronie's disease). The scrotal contents were normal. On rectal examination the prostate was slightly broader than normal. Both lateral lobes were irregular and contained areas of stony hard induration, more pronounced on the right. There was evidence of extension to the apex of the prostate and region of the membranous urethra. Both seminal vesicles were palpable but not indurated. There was no x-ray evidence of bony metastases. The acid phosphatase was normal.

Because of the extension of the disease toward the apex, the condition was considered unfavorable for radical cure at that time. Therefore the patient was begun on diethylstilbestrol 1 mg. per day and maintained on this regimen for almost seven months. During this time serial rectal examinations showed progressive shrinkage and softening of the neoplasm.

On May 27, 1944 the patient was readmitted and prepared for operation. Laboratory studies showed hemoglobin 96, white blood cells 6,100, phenolsulfonphthalein excretion 65 per cent in two hours. The urine was normal except for an occasional white blood cell; culture was sterile.

May 29 a radical perineal prostatectomy was carried out, followed by an uneventful convalescence.

Pathologic studies showed adenocarcinoma of the prostate and involvement of the bases of both seminal vesicles.

The patient was discharged from the hospital on the twenty-ninth postoperative day, voiding a good stream with perfect control. On the last visit, one year after operation, the patient was found to be in good general condition with no evidence of local recurrence or distant metastases. He was passing a stream of good caliber and force.

Case 2.—K. H. B., a white man aged 59, first seen Feb. 3, 1944, came here after a diagnosis of carcinoma of the prostate had been made elsewhere and orchiectomy advised. There was no history of urinary symptoms, weight loss or pain. Previous x-ray studies had been negative for metastases, and acid phosphatase was normal.

On examination the patient was found to be in good condition. The external genitalia were negative. The prostate was slightly broader than normal, fixed, irregular and stony hard throughout. There was evident extension into the apex as well as into the bases of both seminal vesicles.

Radical extirpation was thought to be contraindicated at that time, and the patient was placed on diethylstilbestrol 2 mg. per day. This was maintained for approximately two months. During this time serial rectal examinations demonstrated such satisfactory regression of the carcinomatous process that it was thought advisable to carry out radical perineal prostatectomy. Laboratory studies showed hemoglobin 13.3 Gm., white blood cells 5,600, blood urea 20 mg., phenolsulfonphthalein excretion 75 per cent in two hours. The urine was normal; culture was negative.

April 12, 1944 radical perineal prostatectomy was done. Convalescence was uneventful except for one febrile rise after passage of a sound. The patient was discharged twenty-three days after operation, voiding well and with good control.

Pathologic sections showed extensive adenocarcinoma of the prostate with involvement of the bases of both seminal vesicles.

Four days after leaving the hospital the patient had acute urinary retention and was treated elsewhere for a stricture at the site of anastomosis. A suprapubic cystostomy was done and a urethral catheter left in place. The tube was removed five days later, and the patient was able to void satisfactorily. At the present time the voided stream is free and urinary control satisfactory. The patient has now resumed full activity. He frequently plays eighteen holes of golf a day and experiences no urinary leakage whatever. However, at the end of an especially strenuous day, the patient occasionally notices slight dribbling.

[10] Vallett, B. S.: Radical Perineal Prostatectomy Subsequent to Bilateral Orchiectomy, Delaware M. J. **16**: 19-20 (Feb.) 1944.

Case 3.—Dr. W. N. F., a white man aged 61, a physician, was first examined at the Brady Urological Institute Feb. 11, 1944. In the course of a general physical examination elsewhere the prostate was observed to be hard and irregular. The patient was followed periodically for several months. A bilateral orchiectomy was advised and, on the suggestion of a colleague, he came to the Brady Urological Institute. No nocturia was noticed at any time, and only slight hesitancy. There was no history of pain or weight loss. The patient had a long history of alcohol addiction.

On physical examination the patient was in good general condition. The external genitalia were normal. There was a small, reducible hernia present at the right external ring. Rectal palpation showed the prostate to be moderately broader than normal. It was irregular, indurated and stony hard throughout. The right lobe was especially prominent. The induration had extended into the apex of the prostate and up into the bases of both seminal vesicles. There was no x-ray evidence of metastases. Acid phosphatase studies were normal.

Although the growth had not spread beyond the confines of the capsule, it was thought to be too extensive at that time to insure a complete cure by radical operation. For this reason diethylstilbestrol 2 mg. a day was advised. Rectal examination six weeks later revealed definite regression of the neoplasm both in size and in degree of induration.

The patient was readmitted March 28 and prepared for radical operation. Laboratory studies revealed hemoglobin 12 Gm., white blood cells 5,200, blood urea 20 mg. per hundred cubic centimeters, phenolsulfonphthalein excretion 82 per cent in two hours. The urine was normal; cultures were sterile.

On April 7 a radical perineal prostatectomy was carried out followed by a completely uneventful convalescence except for slight leakage after removal of the urethral catheter on the fourteenth postoperative day. The patient left the hospital nineteen days after operation, voiding well and with good control.

Pathologic studies showed extensive adenocarcinoma of the prostate involving the bases of both seminal vesicles.

Two months later symptoms of urinary difficulty developed, and he required several efforts to empty his bladder. Urinary control, however, was excellent.

He was reexamined July 11. No evidence of local recurrence or distant metastasis was found. However, a stricture had developed at the site of the anastomosis. The residual urine was 30 cc. The patient therefore was readmitted to the hospital and the stricture dilated under spinal anesthesia. He was discharged after several days, voiding an excellent stream and with normal control.

Case 4.—C. E. H., a white man aged 60, first examined at the Brady Urological Institute on March 24, 1944, was referred by his physician, who had followed him for about one year because of increased urinary difficulty and hesitancy as well as an enlarged, rather hard prostate. There had been no history of back or perineal pain and no weight loss.

On physical examination the patient seemed to be in good general condition. The external genitalia were normal. On rectal examination the prostate was moderately broader than normal and especially prominent on the right side. The right lobe was of stony hard induration, especially toward its outer edge and well down toward the apex. The left lobe was firm but not of third degree. The seminal vesicles were thickened but not involved. The growth had apparently extended beyond the capsule on the right side, and particularly into the membranous urethra. Residual urine was 85 cc. There was no x-ray evidence of metastases.

Radical operation was thought to be unjustified because of the extent of the malignant process. The patient therefore was started on diethylstilbestrol 1 mg. per day. He was seen again one month later, at which time he was voiding with considerably less difficulty. Definite regression of the neoplasm had occurred. Diethylstilbestrol was continued another month, and at the end of that time on rectal examination it was difficult to detect any areas of stony hardness or make a gross diagnosis of carcinoma.

The patient was readmitted May 23, 1944 and prepared for radical perineal prostatectomy. Laboratory studies disclosed hemoglobin 100, white blood cells 8,500, blood urea 28 mg. per hundred cubic centimeters, phenolsulfonphthalein excretion 85 per cent in two hours. The urine contained a trace of albumin and 4 to 5 white blood cells. May 24 radical perineal prostatectomy was carried out and followed by an uneventful convalescence. The urethral catheter was removed on the fourteenth postoperative day. The patient voided an excellent stream and remained dry perineally. Pathologic studies showed carcinoma of the prostate not involving the seminal vesicles. It was predominantly adenocarcinoma in type, with a multiplicity of form and showing diethylstilbestrol changes. The patient was discharged nineteen days after operation, voiding well and with good control.

After returning home he did well for about fourteen months. At that time he noticed some diminution in the size and force of the stream. He was reexamined Sept. 6, 1945 and found to be in excellent general condition. There was no evidence of local return of the cancer or distant metastases. A soft stricture at the site of the anastomosis was easily dilated, following which the patient developed acute retention. He was hospitalized twenty-four hours and discharged voiding easily with normal control.

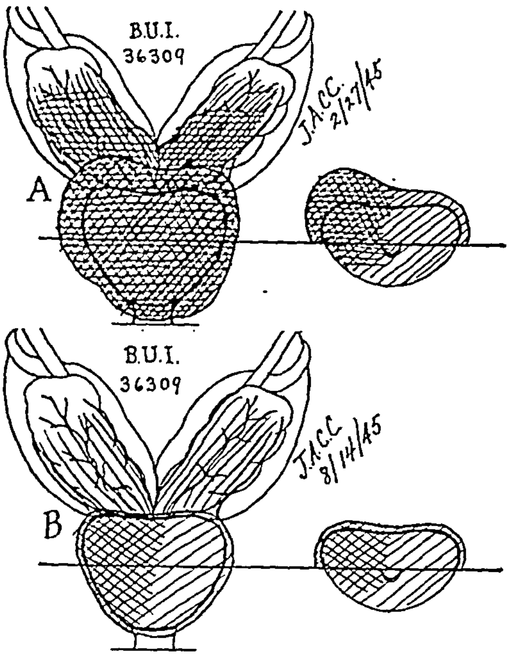

Fig. 1 (case 5).—*A*, diagrammatic representation of rectal findings on initial examination. *B*, six months after institution of diethylstilbestrol.

Case 5.—M. W., a white man aged 68, was first examined at the Brady Urological Institute Feb. 27, 1945. For the preceding year he had suffered from vague gastrointestinal symptoms manifested chiefly by gaseous distention. His local physician had discovered a suggestive nodule in the prostate and referred him to a urologist, who diagnosed carcinoma of the prostate but considered the process too extensive for radical operation. The patient was referred to this clinic. He had no history of any urinary symptoms whatever. Rectal examination disclosed the prostate to be considerably broader than normal. The left lobe was nodular and of stony hard induration, and there was nodularity of the right lobe, which also was stony hard but not quite so prominent as the left. The bases of both seminal vesicles were invaded, particularly on the left (fig. 1 *A*). There was no x-ray evidence of bony metastases. The serum acid phosphatase studies were normal.

The initial impression was that the growth was too extensive for radical operation. Diethylstilbestrol 1 mg. a day was started. When seen six months later a most remarkable change in the palpatory findings had occurred. The gland was only slightly broader and was more prominent than normal. No nodules were present, and the elevation on the left side had disappeared. The entire gland was elastic and compressible and not adherent. The vesicles and the base of the bladder above the gland were quite soft (fig. 1 *B*). Another x-ray again demonstrated no evidence of metastases.

The patient was readmitted Aug. 15, 1945 and prepared for radical perineal prostatectomy. All laboratory findings were negative. August 17, radical perineal prostatectomy was performed. The convalescence was smooth. The urethral catheter was removed the eleventh postoperative day, following which all urine drained by way of the perineum until reinsertion of the catheter on the seventeenth postoperative day. The catheter was finally removed the twenty-second day, after which the perineum remained completely dry. For the first three days the patient was almost totally incontinent, but at the end of that time he regained control gradually, so that when he was discharged on the twenty-sixth postoperative day he was voiding a normal stream with excellent control.

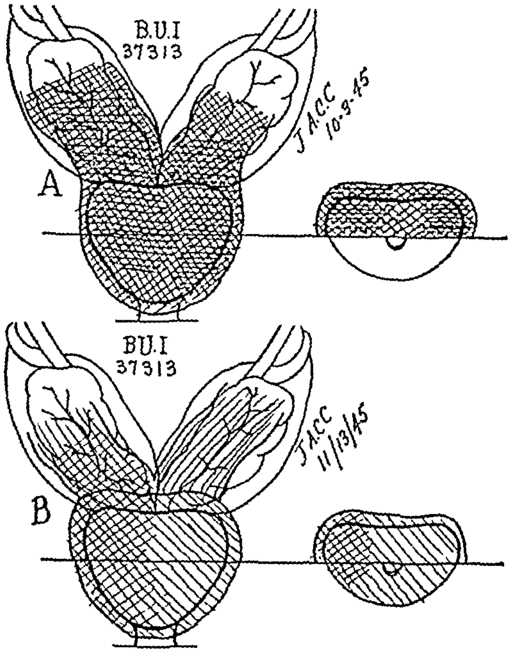

Fig. 2 (case 7).—*A*, diagrammatic representation of rectal findings on initial examination. *B*, six weeks after institution of diethylstilbestrol.

Pathologic studies showed adenocarcinoma of the prostate involving the bases of both vesicles, chiefly the left, with scattered areas of diethylstilbestrol change.

The patient has not been seen since, but a letter from him one month after operation stated that he was in excellent health and voiding satisfactorily.

Case 6.—E. R., a white man aged 62, first seen March 1, 1945, had a history of onset of urinary difficulty and frequency one year prior to the first examination. Six months before examination he had been seen elsewhere and had been treated periodically by urethral sounds and posterior urethral irrigations.

The patient was in good general condition. The external genitalia were normal. On rectal palpation there was evidence of third degree induration and nodularity throughout the prostate, but chiefly on the right side, with infiltration of the perirectal tissues over an area 1.5 cm. in diameter on the right side. Except for this the carcinomatous process seemed to be confined within the capsule of the prostate. There was no x-ray evidence of metastases. No serum acid phosphatase studies were obtained. The patient was placed on diethylstilbestrol 2 mg. per day. On this medication he developed some tenderness and soreness of the nipples, but there was some lessening in frequency and nocturia. The stream was perhaps slightly better. He was again examined May 31, 1945, at which time the prostate felt distinctly smaller. The left lobe was slightly larger than normal, smooth and elastic throughout, and of second degree induration. In the lower portion of the left seminal vesicle there was induration, but the remainder felt soft. The membranous urethra was uninvolved, and the rectal mucosa smooth.

The patient was admitted to the hospital June 2, 1945. General physical examination was essentially negative. Preoperative laboratory studies included hemoglobin 13, 7 Gm.: white blood cells 13,550, blood urea 20 mg. per hundred cubic centimeters, phenolsulfonphthalein excretion 75 per cent in two hours. Urine was normal.

On June 11 radical perineal prostatectomy was carried out. At operation there was obvious extension into the tip of the right seminal vesicle and laterally to the pelvic wall on the right side. After removal of the prostate and seminal vesicles there apparently still remained some neoplastic tissue on the right side. Postoperatively the patient had a smooth convalescence. The urethral catheter was removed on the fourteenth postoperative day, following which the patient voided an excellent stream with good control. On the sixteenth postoperative day he suddenly developed a left hemiparesis, which manifested itself as a seventh nerve palsy and decided motor loss of the left arm and leg. This cleared rapidly after about two weeks and was considered to have originated on an angiospastic basis. The patient was discharged on the thirty-fifth postoperative day, voiding satisfactorily with excellent urinary control.

Pathologic studies showed adenocarcinoma of the prostate with considerable anaplasia and with some diversity of the histologic pattern.

The patient was seen three weeks after leaving the hospital. A soft stricture at the site of the anastomosis was easily dilated. He was again seen after another three weeks period and found to be voiding a good stream with normal control. The patient died in May 1946. His physician said that he could feel some evidence of malignancy on rectal examination.

Case 7.—Dr. W. T. B., a white man aged 70, a physician, was admitted to the Brady Urological Institute Oct. 3, 1945 complaining of nocturia and burning on urination for approximately three to four years. He had been referred by his own physician, who had discovered a hard nodule in the prostate on rectal examination.

On physical examination the patient seemed to be in excellent general condition. The external genitalia were entirely normal. On rectal examination the prostate was somewhat broader than normal. Both lateral lobes were irregular and stony hard throughout, with the induration extending into both seminal vesicles, particularly on the left side (fig. 1 *A*). Laboratory studies revealed hemoglobin 14 Gm., white blood cells 9,600, blood urea 20 mg., phenolsulfonphthalein excretion 73 per cent in two hours. The urine contained 8 to 10 white blood cells per high power field; cultures were sterile. There was no x-ray evidence of bony metastases.

It was believed that, although this could be classed as a moderately advanced carcinoma of the prostate which had extended into both seminal vesicles, the radical operation should be deferred in the hope that following a course of diethylstilbestrol, the growth would regress sufficiently to permit an easier operative procedure and insure a better functional result. The patient was discharged and placed on diethylstilbestrol 2 mg. per day.

He was readmitted to the Brady Urological Institute for the second time on Nov. 13, 1945. Rectal examination disclosed the prostate to be only slightly broader than normal. The right lobe was smooth and firm but elastic and compressible throughout. The left lobe contained no evidence of stony hardness and was also smooth and compressible (fig. 2 *B*). There had been a very definite and gratifying response to diethylstilbestrol therapy. It was decided that the patient was now suitable for radical operation. Preliminary laboratory studies revealed hemoglobin 14.2 mg., white blood cells 8,700, blood urea 20 mg. per hundred cubic centimeters. The voided urine contained 4 to 6 white blood cells per high power field.

Nov. 14, 1945, radical perineal prostatectomy was carried out The postoperative course was *entirely uneventful.* The urethral catheter was removed the twelfth postoperative day, following which the patient voided a good stream with excellent control. The patient was *discharged sixteen days after operation,* to be followed by his own physician

Pathologic studies showed adenocarcinoma of the prostate, fairly well differentiated, *with involvement of both seminal* vesicles

Several weeks after leaving the hospital the patient developed acute retention and was seen by a urologist elsewhere who, after several dilations, performed a transurethral resection Following this procedure the patient became totally incontinent, but this condition has *gradually improved, so that he now has* no nocturnal leakage but has to wear a clamp during his surgical activities, which he has resumed

SUMMARY

Endocrine therapy in the treatment of carcinoma of the prostate, either by the administration of estrogen or by orchiectomy or by a combination of the two, has been proved by many competent observers to have a definite and most valuable place in the treatment of carcinoma of the prostate. Regression of the primary growth, as measured by rectal examination, has been noted to occur in approximately 75 per cent of the cases, and regression of metastases in 45 per cent. It has been postulated that this inhibitive effect results from an interference with the enzyme balance by endocrine therapy, and probably this effect is more pronounced on the younger, actively growing cells of the tumor, which are more dependent on androgen for their metastases. In spite of the intensive laboratory studies and many clinical observations that have been made on endocrine therapy of carcinoma of the prostate, no case has yet been reported in which complete disappearance or clinical cure has been obtained by endocrine therapy alone. From the results of experimental laboratory work and clinical research, it would appear at present that a permanent cure with endocrine therapy of carcinoma of the prostate cannot be obtained.

The regression of the prostatic growth which occurs in an appreciable percentage of cases under endocrine therapy has led us to follow a series of 7 cases in which on first examination the growth was considered too far advanced for complete extirpation by radical operation. In these 7 cases it was considered that the regression of the neoplasm as far as could be judged by rectal palpation had progressed to a sufficient degree to permit, the radical operation which was successfully carried out in these cases. There has been no operative mortality in this series, but 2 patients have developed complications resulting from stricture formation at the site of the anastomosis. One patient has died of recurrence and metastases one year after operation.

The patients in this series have all been operated on within the last two years, so that the presentation is in no sense intended as a study of ultimate mortality.

It is our impression that endocrine therapy for the preparation of patients to undergo the radical operation is of the utmost value in that:

1. We have observed numerous cases of moderately advanced carcinoma of the prostate in which orchiectomy or transurethral resection has been advised in the belief that the disease was too far advanced for radical extirpation.

2. Regression of the growth, which usually occurs, materially facilitates the operative technic in moderately advanced cases.

3. It is our hope that five year cures will be obtained in some of the cases in which on physical examination the observer's opinion was that the prognosis for radical cure was unfavorable.

In view of the regression of the primary growth which usually occurs in cancer of the prostate following endocrine therapy and which is attributed to death of at least some of the malignant cells, presumably at the periphery of the lesion, it would seem advisable to institute endocrine therapy in all cases of carcinoma of the prostate, even those which fulfil the criteria for the radical operation.

ORTHOPEDIC CAUSES OF PELVIC PAIN

HORACE C. PITKIN, M D
San Francisco

This paper presents the problem of pelvic pain in a deliberately simplified form. My purpose is to show that measurements of pelvic mobility are essential to an accurate diagnosis.

The fundamental structure of the pelvis consists of bones, muscles and joints. The massive ring formed by the two innominate bones and the sacrum gives origin and insertion to the most powerful muscles in the body; muscles that go far afield for attachment to other bones. The intrapelvic sacroiliac joints and symphysis pubis allow the bony ring to change its shape. The extrapelvic hip joints, sacrolumbar and sacrococcygeal joints allow motion of other bones on the pelvic ring. The ligaments of the pelvic joints are tremendously strong and are elaborately arranged in all planes, so that the slightest change in the position or shape of the pelvic ring alters the total ligamentous tension.

Flexion and extension are the normal motions of the intrapelvic joints (fig. 1). The sacrum may flex or extend on the ilia at the sacroiliac joints. The axis of sacral motion is a horizontal, transverse line that passes through the ligamentous portions of the sacroiliac joints and the body of the second sacral vertebra. Sacral flexion increases the lumbar lordosis, narrows the pelvic inlet and enlarges the outlet: sacral extension reverses the process. Furthermore, either innominate bone may flex or extend on the other at the symphysis pubis. The axis of innominate motion is a horizontal, transverse line that passes through the center of the symphysis. Innominate flexion by elevating the ilium produces lateral tilting of the sacrum and by carrying the ilium forward produces rotation of the sacrum toward the opposite side: innominate extension reverses the process. Abnormal motion may occur when the symphysis pubis is relaxed or torn, allowing a small amount of opposed flexion and extension of the innominate bones at the hip joints. Abnormal motion appears in appropriate roentgenograms as a vertical shift at the symphysis pubis.[1]

The curve of intrapelvic mobility is high at birth, goes down slightly during childhood and rises to a peak at puberty. During adult life the curve gradually descends, and it remains at a low level during old age. Age and other factors, such as training and build, influence articular mobility in general, but the action

---

Read in a symposium on "Pelvic Pain" before the joint meeting of the Section on Obstetrics and Gynecology and the Section on General Practice of Medicine at the Ninety Fifth Annual Session of the American Medical Association, San Francisco, July 5, 1946

[1] Chamberlin, W. E: *The Symphysis Pubis in the Roentgen Examination of the Sacro Iliac Joint,* Am J. Roentgenol. **24:** 621, 1930.

of the female sex hormones on the intrapelvic joints is more specific. The puberty peak is higher in women than in men, and the subsequent descent is more gradual. There is a minor peak before each menstrual period, and the peak at parturition is approximately twice the height of the puberty peak. The return to normal mobility after delivery parallels the curve of uterine involution. The flexion-extension range of the innominate bone varies between 2 and 30 degrees. The average range in young, adult males is 5.5 degrees.

The intrapelvic joints have three functions: stability in weight-bearing; mobility in child-bearing and the reflex maintenance of balance. Stability is the most important of the three, and complete bony ankylosis of the intrapelvic joints affords a good illustration. In ankylosis stability is maximal, mobility is nil and the intrapelvic joint sense of position and movement is lost. Yet if fusion has occurred in normal alignment there may be no interference with parturition or balance. The function of mobility is relatively unimportant, even in a difficult delivery, but excessive mobility is a handicap because it interferes with stability and balance. Aching joints and clumsiness are commonly found in pregnancy and adolescence as the results of excessive mobility. The part played by the intrapelvic joints in the reflex maintenance of balance is extremely important, as long as the joints are movable. When motion ceases, as in ankylosis, the function of balance passes on to adjacent structures.

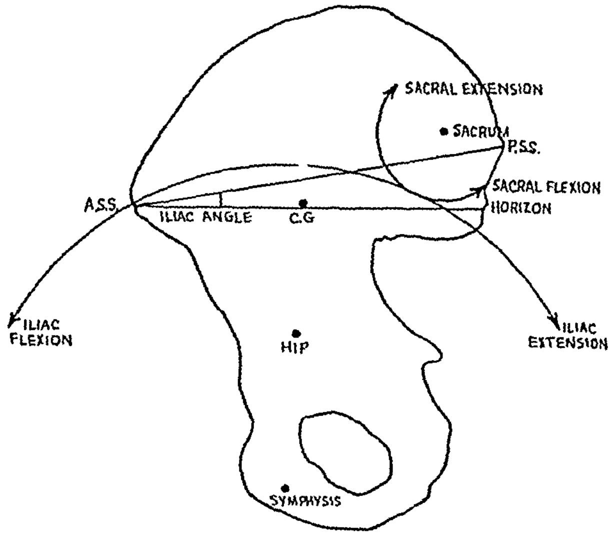

Fig. 1.—Centers of gravity and pelvic motion. A. S. S. and P. S. S., anterior and posterior superior spine; C. G., center of gravity.

All movements of the body in equilibrium revolve about the center of gravity. This point normally lies at the center of the pelvis, just below the promontory of the sacrum. Any shift of the center of gravity tends to change the shape of the pelvic ring. Thus, the intrapelvic joints are the first to be affected by a disturbance of equilibrium. Motion of the joints produces a change in the tension of the pelvic ligaments from which streams of proprioceptive impulses arise. The impulses travel in every spinal nerve from the first lumbar to the fourth sacral and provoke a widespread reflex response. When the weight of the body is supported on the feet, a shift of the center of gravity in any direction produces a protective reflex movement of the pelvis in the opposite direction that tends to return the center of gravity to its normal position.

One of the functions of a ligament is to initiate self-protective reflexes that preserve it from excessive tension. For example, the average person has slipped and turned an ankle many a time, but the protective reflex usually bounced the ankle back before a ligament was sprained. Such a reflex always tends to relax the ligament, regardless of the type of the initial stimulus, be it tension, trauma, inflammation or whatever. Thus, when a pelvic ligament is insulted, it evokes a powerful protective reflex that tends to relieve it of weight-bearing. It has been seen that such a reflex moves the pelvis away from the center of gravity, and if the insult persists the continuing muscle spasm tends to maintain the abnormal pelvic position. The ability of the pelvic reflexes to return the center of gravity to its normal position without the intervention of more distant, and consequently less efficient, reflexes is a determining factor in normal posture. If the pelvic reflexes are not competent to maintain equilibrium, the function is passed along to the spine and lower extremities. Scoliosis and other postural defects are produced. Later results of the imbalance are spreading reflexes, disturbed function in other joints, atrophies and contractures.

Under certain circumstances a powerful protective reflex may be initiated by a stimulus so weak that it causes no alarm in consciousness. Under other circumstances an equally weak stimulus may be so facilitated in the central nervous system that it appears in consciousness as pain. Somewhere between the two extremes lies the normal condition, in which a stimulus, to cause pain, must be sufficiently intense to threaten the integrity of structure or function. Disturbances of pelvic structure and function usually are immediately painful, but the reflex protection is so powerful that the full extent of the damage may not be appreciated for years. The typical story is, "I had a twinge of pain right here (pointing), but I didn't pay much attention to it. The next morning, I had pain all over here (rubbing), and I couldn't get out of bed." Thus it is apparent that the first pain tends to be sharply localized, but so evanescent that it often is forgotten. Later pain is more diffuse, dull and aching in character. If the affected structure receives only a few sensory fibers from a spinal nerve, the painful stimulus also may be referred in consciousness to the major sensory distribution of the nerve. The typical story is, "I thought some one had stuck a knife in my back, and I looked around to see who hit me. It shot down my leg like a streak of lightning on a red hot wire, and now the whole back of the leg kind of aches." Here again, the original twinge is well localized and the original reference is sharply delimited, but the subsequent referred pain is diffuse.

Referred pain typically originates in structures that receive little or no sensory supply from the spinal nerves. This type of structure includes most of the denser connective tissues, such as scars, fascias, ligaments and joint capsules, as well as blood vessels and viscera. The injection of a few drops of a 6 per cent solution of sodium chloride into such a structure produces a harmless but temporarily painful sensory stimulus. The method is useful in mapping out areas of referred pain. In general, when the afferent impulse travels in a single spinal nerve any referred pain tends to appear in the corresponding dermatome, or major sensory distribution of the nerve. Therefore, in theory, a pain referred to dermatome x should infallibly reflect a disturbance in ligament y or in joint z, if y and z are the only structures entirely supplied by sensory fibers from nerve x. The theory seldom works, for several reasons. A quantitative increase in the painful stimulus, such as the injection of more than a few drops of the hypertonic solution, may cause the afferent impulses to spread within the spinal cord. Thus, a pain referred to the posterior division of a spinal nerve may gradually spread to the anterior division or to adjacent segments. The dermatomes may be so small and so crowded together as to be practically indistinguishable, a condition that occurs in the buttocks and sacral region. A structure that is supplied by several nerves may refer pain to several small dermatomes without producing a specific pattern. Finally, pelvic pain may arise in a wide variety of structures, in the trunk, in the pelvis or in the lower extremities, all of which refer pain to the same area. Consequently the pain itself is of little value in differential diagnosis, unless it involves extrapelvic areas in which the dermatomes are more discrete.

The pelvic pain that regularly accompanies physiologic relaxation of the female pelvis is so common that many women accept it as being unavoidable. Measurements of intrapelvic mobility in men who complain of pelvic pain from all causes show that the average amount of motion is one-third higher than normal. It follows that relaxation of the intrapelvic joints is the commonest cause of pelvic pain. Other common causes appear in the following list, from which disturbances of the nervous system, blood vessels and viscera have been omitted.

1. Disturbances in the function of the pelvic joints, muscles and ligaments, such as strains, sprains, sacroiliac slips and symphysial subluxations.
2. Disturbances in the function of the lumbar joints, muscles and ligaments, such as strains, sprains and zygapophysial subluxations.
3. Structural changes in the pelvis and lumbar spine, such as those produced by congenital defects, fractures, degeneration of intervertebral disks, arthritis, suppurative diseases and neoplasms.
4. Disturbances in the structure and function of the lower extremities, such as flatfeet.

In the physical examination of patients who complain of pelvic pain, areas of tenderness frequently are found in the joints, muscles, fascias and ligaments of the trunk and lower extremities. When pressure on such an area produces or aggravates the referred pain, an injection of procaine hydrochloride into the point of maximum tenderness is indicated. If the injection relieves the pain, one may assume that the site of origin has been found. Unfortunately, many of the pelvic and spinal structures are not readily accessible to palpation or injection, and a determination of function is necessary. If the suspected structure is a muscle, fascia or ligament, it should be put under tension in an endeavor to reproduce the pain. Many special tests have been devised for this purpose, such as straight leg raising and prone knee flexion. If a joint is suspected, it should be carried through its full range of motion; the motion should be measured, and the measurement should be compared with that of the normal joint. Any pain, crepitus or adventitious sound produced in the course of the examination should be noted. Without an examination of this sort, an accurate estimate of articular function is almost impossible. The procedure is standard elsewhere in the body, but hardly any one, except an orthopedic surgeon, applies it to the intrapelvic joints.

To the best of my knowledge, the medical literature contains only one description of a method for measuring flexion and extension of the innominate bones.[2] In this method the production of motion is accomplished by inserting a 1½ inch (4 cm.) lift under one of the subject's feet, meanwhile instructing him to keep both knees straight and both heels down to eliminate compensation in the lower extremities. The lift produces a shift in the center of gravity that cannot be completely compensated by the pelvic reflexes alone. Therefore the full extent of intrapelvic compensation is achieved before the spinal reflexes are called on to preserve equilibrium. In other words, the intrapelvic joints are carried to one extreme of allowable motion, the innominate bone on the lower side flexing and that on the higher side extending. The production of motion is entirely reflex and does not depend on the subject's volition. Measurements are taken with an inclinometer (fig. 2) to determine the angle of iliac inclination on each side. This angle is defined as the angle formed by the plane of the floor and the projection of a straight line that passes through the anterior-superior and posterior-superior spines of an ilium. Innominate flexion increases the angle and extension decreases it (fig. 1). When the reading for each ilium has been taken, similar measurements are taken with the lift under the other foot. The difference between the two readings on each side represents the complete flexion-extension range of each innominate bone.[3] The entire procedure is simple, brief and applicable to any patient who can stand erect without support.

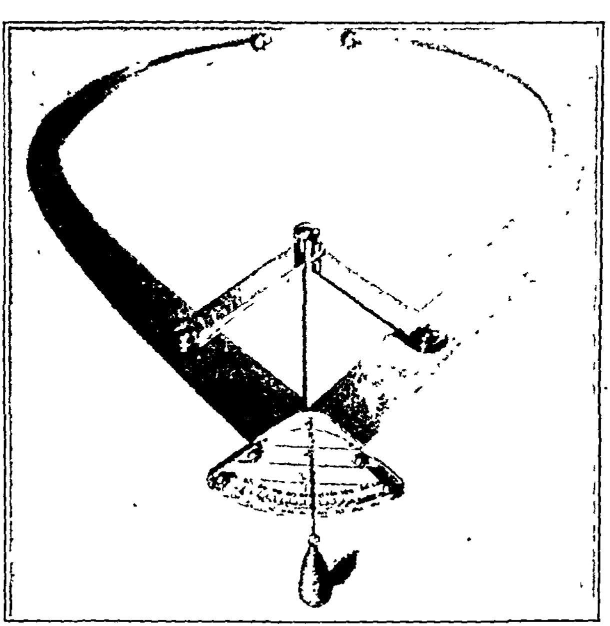

Fig. 2.—An inclinometer.

Structural changes in bones and joints usually appear in roentgenograms, but many functional changes do not. Symphysial and zygapophysial subluxations are demonstrable on routine films, but the technic of visualizing sacroiliac slips is slow and expensive, as compared with clinical measurements. One case in particular will serve to illustrate the need for inclinometric measurements. When a sacroiliac slip locks the two bones in flexion, the stability of the joint is usually increased and there may be little alteration in the ligamentous tension. Consequently the symptoms may be so mild that the incident is soon forgotten, but the structural imbalance remains. The function of balance passes to the opposite joint, which gradually acquires compensatory relaxation and increased mobility. If the slip occurs in childhood and is not promptly corrected, a structural scoliosis may develop as the child grows. Furthermore, when symptoms of strain begin to appear the pain is often related to the movable joint, and the slip may be entirely overlooked. In this case an error in diagnosis may lead to a permanent deformity, but in every case of pelvic pain an accurate estimate of pelvic function is essential to an accurate diagnosis. An inclinometer is the instrument of choice for quickly determining that the intrapelvic joints are locked, are relaxed or are functioning normally.

[3] Provided, of course, that any simultaneous flexion or extension of the innominate bones at the hip joints must be subtracted from the result.

SUMMARY

Pelvic pain may arise from disturbances in the structure and function of the bones, joints, muscles, ligaments and fascias of the trunk, pelvis and lower extremities. (Disturbances of the nervous system, blood vessels and viscera are not discussed.) The relaxation of the pelvic joints that precedes menstruation and accompanies pregnancy is the commonest cause of pelvic pain. A clinical method for measuring the motion of the intrapelvic joints is presented, with the conclusion that an accurate estimate of pelvic mobility is essenial to an accurate diagnosis.

909 Hyde Street.

ABSTRACT OF DISCUSSION

Dr. C. Frederic Fluhmann, San Franciso: Dr. Pitkin has given a splendid, simplified analysis of orthopedic causes of backache, a symptom of frequent occurrence in obstetric and gynecologic patients. As he pointed out, backache is an exceedingly frequent observation during pregnancy and also in women just before, during and occasionally just after menstruation. This is due to a preternatural mobility of the pelvic joints, and there is good reason to believe that it is an endocrine disturbance. Hisaw years ago showed that the injection of a corpus luteum extract produced an extensive relaxation and separation of the pelvic joints of guinea pigs. When one discusses backache in gynecologic patients, one subject always comes up, and that is the role that retroversion of the uterus plays in the causation of backache. As the years have gone by, it has become apparent that in an uncomplicated retroversion backache is seldom the result of that lesion. In most institutions there has been an extensive diminution in the number of plastic operations, but one must face the fact that in the country at large there are still far too many suspensions of the uterus being performed for backache and unjustifiable indications. Backache accompanies many lesions of the pelvis, for example, certain types of fibromyomas, endometriomas and pelvic inflammatory disease. However, I should like to call attention to an ailment which produces pain in the lower part of the abdomen and in the back and is due to a low grade inflammatory condition of the parametrium. Its chief anatomic feature is a decided thickening and tenderness of the sacrouterine ligaments. This may easily be missed on vaginal examination but is readily demonstrated by a rectovaginal examination.

Dr. J. W. Davies, New York: The treatment of pelvic pain requires a broad comprehension to properly evaluate its source. It has been shown how important the well trained general practitioner is in properly evaluating the cause of pain. It is he who should refer the patient to the proper specialist for specific treatment. The psychiatrist has had satisfactory results in treating some cases of pelvic pain. The urologist and the orthopedist have frequently relieved pain after the gynecologist has been unable to do so. Each specialist is sincere, but because of overspecialization the comprehension of the case is frequently narrowed. Meetings such as this tend to increase one's perspective by suggesting that there may be a single factor common to all the specialties which may be of aid in treatment. One important cause of pain is the layer of tissue which lies superficial to the peritoneum. This layer is erroneously called the subperitoneal tissue, and because of the misnomer insufficient attention has been directed toward its study. This preperitoneal tissue envelops the kidney, ureter, bladder and the urethra, also the uterus, cervix and the vagina. The rectum likewise is encapsulated by this tissue, which permits independent gliding of the various systems. If there is an abnormal slipping of an abdominal or pelvic organ traction may be deflected to another, more sensitive, organ, which may cause pain even though it is not primarily at fault. The enveloping preperitoneal tissue runs to the lateral pelvic wall, and it is possible to trace the fibrous portion through the sacroiliac joint into the dimple of the subcutaneous tissue of the back. A slipping of the sacrum on the ileum, such as Dr. Pitkin has demonstrated, may cause traction on the preperitoneal tissue and thereby angulate or compress pelvic nerves. If the pain is referred down the leg its treatment is relatively simple, but if pain is referred to a pelvic organ it is more difficult for the patient to choose the specialist to be consulted. During menstruation the various joints become relaxed, and it is this relaxation of the joints which may cause sacroiliac hypermobility and the resultant menstrual backache. Pelvic congestion may angulate pelvic nerves and cause direct or referred pain. Infections of the urethra, cervix and uterus are drained by the pelvic lymphatic vessels, which are in the preperitoneal tissue. The diseased lymphatics may angulate the ureter or set up a secondary neuritis in the adjacent nerves.

Dr. Douglas Campbell, San Francisco: Recent investigations have shown that the two types of pain which are experienced—superficial or "bright" and deep "dull" or aching—arise from dermatomic and mesodermal tissues respectively. The dermatomic variety is rather easily localized; the mesodermal is diffuse, follows the myotomes or sclerotomes and consequently may be referred a considerable distance. Furthermore, pain arising from viscera or skeletal structures is frequently indistinguishable, so that a lesion of the back may be perceived as intra-abdominal or a diseased pelvic viscus may give rise to pain in the back. Neurologically, all varieties of pain are initiated by similar receptors, but deep pain traverses smaller fibers; reaching the cord and brain stem the impulses ascend spinothalamic pathways to the thalamus, whence they are relayed to appropriate cortical regions for appraisal and localization or to hypothalamic and lower reticular stations for autonomic and other reflex purposes. Pain impulses, in particular those of visceral or skeletal origin, are also stepped up in intensity and radiated to neighboring or remote structures through closed and open circuiting in the internuncial pools of neurones in the cord, stem and higher forebrain levels. Because of augmentation by the reverberating activities of internuncial pools and the autonomic functions of the diencephalon, prolonged protective spasm of neighboring muscles and reactions of the viscera occur. The autonomic features may lead to disturbances of personality, such as depression, irritability, loss of libido and anorexia with its consequences of malnutrition. Protective muscular spasm gives rise to more pain and increased autonomic disturbances. Vicious circles are thus established, the intensity and variation of which will depend to a great extent on the neuropsychic makeup of the patient. Some persons are more stable; others, who have lower pain thresholds or a neurotic disposition, are less stable and likely to over-react to even slight lesions of pain-sensitive structures. In persons of this latter group there frequently develops overtense musculature, particularly of the lower part of the back, due to anxious feelings about menstruation or other matters which concern their sexual life, and this, augmented usually by faulty posture and malnutrition, may lead to the perception of pain or at least discomfort, the misinterpretation of which under the pressure of neurotic attitudes stirs up more anxiety and establishes the vicious circle: pain—anxiety—increased tension—increased anxiety and so on.

Dr. Horace C. Pitkin, San Francisco: The discussion of this paper for the first time has begun to give an all-around picture of pelvic pain. A gynecologist and a psychiatrist have discussed it, and there has been an attempt to correlate and group together all the various conflicting factors of pelvic pain that make the problem so complex and so disturbing. I don't believe that anyone failed to make himself perfectly clear or that there are any questions that need to be answered

NERVOUS PATHWAYS INVOLVED IN PELVIC PAIN

Some Anatomic and Physiologic Aspects

ROBERT B. WILSON, M.D.
and
ROBERT D. MUSSEY, M.D.
Rochester, Minn.

In this symposium on the subject of pelvic pain, a review of the basic anatomy and physiology of the nervous pathways of pain in general and of pelvic pain in particular will assist toward a more nearly complete understanding of the various clinical entities which may give rise to this symptom.[1] For a number of years most of the attention given to the subject of pain arising in the pelvic organs has been centered on the autonomic nervous system, which supplies these organs. It is obvious, however, that pain which arises in the pelvis may be somatic or visceral, or both, in origin. In this brief review the anatomy of both avenues of innervation will be considered and mention will be made of some of the concepts of the physiology of pain (see the accompanying illustration [1]).

SOMATIC INNERVATION

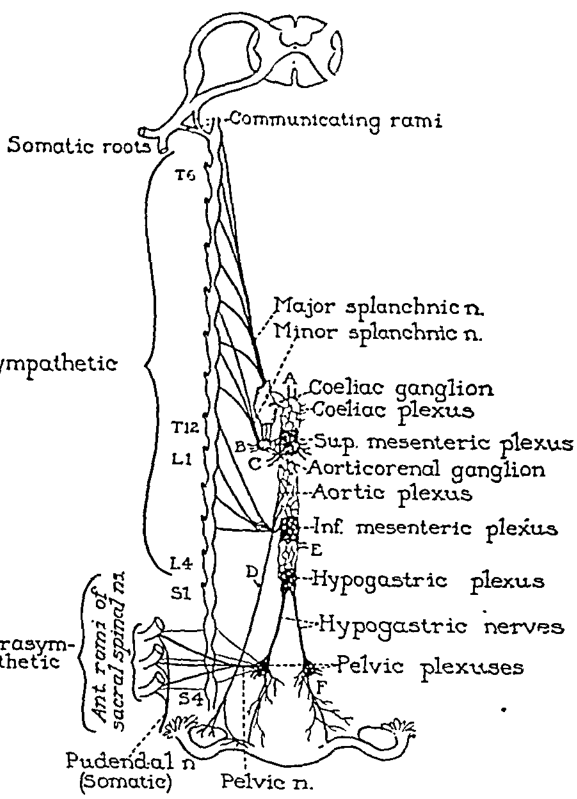
The term somatic innervation applies, of course, both to the sensory and the motor nerve supply to the frame of the body. The concern at this time is with the sensory somatic innervation, and it will be necessary to recall in general the origin and course of a sensory nerve. A spinal nerve arises from a segment of the spinal cord and is composed of an anterior (motor) root and a posterior (sensory) root. In the posterior nerve root is found the spinal ganglion, in which are located the nutrient cells of the sensory apparatus. This ganglion will be mentioned again in connection with the so-called sympathetic sensory nerves. After a short course as a single nerve trunk, each spinal nerve divides into anterior and posterior branches (or rami) which contain both sensory and motor components. Thirty-one such spinal nerves comprising eight cervical, twelve thoracic, five lumbar and five sacral nerves and one coccygeal nerve are present on each side of the body.

The posterior and anterior rami which arise from the mixed spinal nerves at the intervertebral foramina pass dorsally and ventrally, respectively. The posterior branches are relatively short and supply somatic structures on the dorsal surface of the body. The anterior branches, on the other hand, have a much wider distribution. They run independently in the thoracic region, but in other regions they anastomose freely to give rise to the complicated cervical, brachial and lumbosacral plexuses.

The anterior rami from the lumbar and sacral portions of the spinal cord and the coccygeal nerve forming the lumbosacral plexus probably constitute the group of nerves which have the most significance as far as interpretation of pelvic pain of somatic origin is concerned.[2]

There are short, direct branches which supply such muscles as the quadratus lumborum and the psoas major and psoas minor. The iliohypogastric nerve furnishes part of the supply to the transverse and internal oblique abdominal muscles, together with terminal branches to the peritoneum and to various cutaneous areas, including those over the lateral and upper portions of the iliac crest. The ilioinguinal nerves supply branches to the abdominal muscles, the peritoneum, cutaneous areas of the upper and medial parts of the thighs and, by labial branches, the mons pubis and the labia majora.

Branches from the femoral nerve in part supply the iliac and iliopsoas muscles. By other branches these nerves also supply fibers to the hip joint and cutaneous fibers to the anterior surface of the thigh. It is to be understood that all branches of some of these nerves are not mentioned because they do not apply to the subject under discussion. Another important nerve which arises from the lumbosacral plexus is the obturator



Anatomic distribution of the somatic and autonomic nerve fibers of concern to the gynecologist. *A*, Fibers to esophagus, stomach, duodenum, pancreas, liver, gallbladder and spleen; *B*, to kidney; *C*, to small intestine, cecum, ascending and transverse colon; *D*, to ovary and fallopian tube; *E*, to sigmoid and descending colon; *F*, to rectum, bladder and uterus. Somatic roots supply the abdominal wall and the parietal peritoneum. The pudendal nerve supplies the perineal structures.

nerve. This nerve gives off a branch to the external obturator muscle before dividing into anterior and posterior terminal branches which supply adductor muscles and cutaneous surfaces of the medial aspect of the thigh; the anterior branch gives off a branch to the hip joint.

That portion of the lumbosacral plexus known as the sacral plexus is formed from the anterior branches of the fourth and fifth lumbar and first to third sacral nerves. The pudendal plexus, which can be considered as a part of the sacral plexus, arises from the first four sacral nerves and supplies nerves to the pelvic viscera and to the muscles and skin of the perineum. The sacral plexus lies in the pelvis on the anterior surface of the pyriformis muscles. It sends branches to the pelvic girdle and to the lower extremity. Only the former will be mentioned.

Muscular branches are given off to the pyriformis, obturator internus, gemellus and quadratus femoris muscles. The superior gluteal nerve supplies branches to the gluteal muscles. The inferior gluteal nerve also supplies the gluteus maximus. The posterior femoral cutaneous nerves, by inferior clunial branches, supply the skin over the lower and lateral portions of the buttocks and, by perineal branches, furnish some of the sensory fibers of the perineum and of the posterior surfaces of the labia majora. From the pudendal plexus, which is situated in the lower part of the sacral plexus, muscular branches are given off to the levator ani and coccygeal muscles; visceral branches are given off to the rectum, bladder and vagina by the middle hemorrhoidal, inferior vesical and vaginal nerves. These visceral branches may go to their viscera directly or after union with the sympathetic plexuses.

The pudendal nerves leave the bony pelvis on the medial aspects of the ischial tuberosities, where they divide into the perineal and clitoral nerves. Just before this division they give off the inferior hemorrhoidal nerves, which supply the external anal sphincter and the skin of the anus. The perineal nerves give off superficial and deep branches. The superficial branches are the posterior labial nerves, which supply the skin of the perineum and the labia majora; the deep branches supply the superficial transverse perineal muscles and the bulbocavernosus. The dorsal clitoral nerves send branches to the deep transverse perineal muscles, to the urethral sphincters, to the clitoris and to both the major and minor labia.

VISCERAL INNERVATION

Visceral innervation is effected by the autonomic, or involuntary, nervous system. A survey of the writings of authorities[3] concerning the nerve supply of the viscera leads to the following conceptions:

The autonomic system can be classified on an anatomic basis into cranial autonomic, sympathetic proper and sacral autonomic components. It is worth while to note that the term sympathetic nervous system is properly applied only to that portion of the autonomic system which lies in the thoracolumbar region. Functionally, the cranial and sacral divisions are commonly called the parasympathetic system. In general the sympathetic and parasympathetic systems have antagonistic actions on organs which they both supply.

Another generalization in regard to the two systems is that in the sympathetic system the excitor cells usually are located in ganglions which are at a distance from the organs which they supply, and the excitor cells of the parasympathetic system are located in or adjacent to the organs which they supply. The excitor or efferent functions of the autonomic nervous system are of great importance and are generally known and understood. The portion of the autonomic system that is known as the sympathetic system begins with cells found in the lateral horns of the gray matter of the twelve thoracic and first two lumbar segments of the spinal cord.

These cells give rise to fibers which leave the cord via the anterior nerve roots to enter the mixed spinal nerves, from which they enter the anterior rami of the spinal nerves. The fibers then leave the anterior rami, forming the white rami communicantes, to enter ganglions of the lateral sympathetic chain, in which they end. These fibers from the lateral horn cells which pass to the sympathetic ganglions are known as connector, or preganglionic, fibers and are medullated. They may end in ganglions that are adjacent to their nerve root of origin or they may pass up or down the sympathetic chain to end in more distal ganglions. The connector fibers unite with excitor cells which are located in the ganglions. From these cells come the postganglionic, nonmedullated excitor fibers, some of which pass peripherally to supply visceral structures and some of which return to their corresponding spinal nerves as gray rami communicantes, to be distributed with branches of the spinal nerves to somatic structures. It is because of this latter fact that the sympathetic supply to the skin is segmental in character. By these postganglionic fibers are effected changes in the caliber of blood vessels, activity of sweat glands, control of functions of the bladder and bowel, regulation of the force and rate of contractions of the heart and other similar physiologic activities.

That this system also has afferent neurons and that the efferent excitatory effects occur following receipt in the central nervous system of afferent impulses is often forgotten. These afferent fibers have a fundamental arrangement similar to that of the somatic sensory neurons. The nutrient cells for the afferent fibers, which were previously mentioned, are found in the posterior root ganglions. The fibers from the viscera find their way to the central nervous system over the same anatomic route as that traveled by the autonomic, efferent, excitatory fibers, except that the fibers from the viscera enter the spinal cord through the posterior nerve roots. It is the current opinion that those afferent neural fibers which are concerned with transmission of the sensation of pain are true sensory fibers and should not be considered as part of the autonomic nervous system except from the anatomic point of view. Thus, if this view is held, it becomes incorrect to speak of sympathetic sensory nerves. One must make a distinction between the afferent nerves concerned with purely autonomic functions and those concerned with the transmission of pain. From this description it follows that pain impulses which arise in the pelvic viscera are transmitted by sensory nerves which travel in the anatomic sympathetic system but which physiologically are not part of it.

The sympathetic supply to the pelvic viscera is formed by preganglionic, connector fibers which pass through the sixth to the twelfth sympathetic ganglions to form the major and minor splanchnic nerves. After these have passed through the celiac ganglion they form the celiac plexus. This plexus lies on the abdominal aorta just behind the pancreas. Fibers from the celiac plexus pass downward to form, successively, the superior mesenteric plexus, the aortic and intermesenteric plexuses and the inferior mesenteric plexuses, all of which lie on the abdominal aorta. The inferior mesenteric plexuses receive additional fibers from those portions of the lateral sympathetic chain which extend from the twelfth thoracic to the third lumbar ganglion. Farther down, at the bifurcation of the aorta, the fibers enter the region of the interiliac trigone to form the superior hypogastric (presacral) plexus at the levels of the fourth and fifth lumbar vertebrae. The superior hypogastric plexus also receives fibers via each of the four lumbar sympathetic ganglions.

From the superior hypogastric plexus, fibers descend to the pelvic viscera in a varying manner. It is the opinion of most writers on the subject that only rarely is there a single presacral nerve. Curtis and his associates [3c] stated that in 20 per cent of cases there was fusion into a single nerve; however, Weinstein [3f] found the single nerve to exist in but 4 per cent of his dissections, while there were bilateral nerve cords in 8 per cent and a plexus pattern in 88 per cent.

Below the sacral promontory the superior hypogastric plexus becomes the middle hypogastric plexus, and the latter divides at the level of the first sacral vertebra to form the bilateral inferior hypogastric plexuses. These continue downward and laterally along the pelvic wall, and at the level of the third sacral vertebra they receive fibers from the sacral plexus. These fibers from the sacral plexus represent the parasympathetic portion of the autonomic nervous system and are known as the nervi erigentes. These are the source of parasympathetic innervation to the uterus, tubes, ovaries and the walls and internal sphincters of the bladder and rectum.

From this description it is obvious that the inferior hypogastric plexus forms the anatomic pathway for both sympathetic and parasympathetic systems in this portion of the pelvis. However, there is no known physiologic or anatomic junction of the two parts of the autonomic system in this vicinity. From a point in the vicinity of the posterior ends of the uterosacral ligaments, the fibers of the inferior hypogastric plexus descend over the rectum to join the plexus of the pelvis. This plexus is also called the ganglion of Frankenhäuser and the uterovaginal plexus. It is located on the posterior surface of the base of the broad ligament, just lateral to the lateral vaginal fornix. From this plexus the uterus, bladder, vagina and rectum receive their sympathetic nerve supply.

The ovaries, as would be expected when their embryologic origin high in the abdomen is considered, receive their sympathetic nerve supply from fibers which reach them along the ovarian arteries and which come from the aortic plexus. The uterine tubes also receive their sympathetic supply from fibers which pursue the same anatomic course. The neural components which supply the ovary originate mainly from the tenth thoracic nerve, while those which supply the tubes are from the eleventh and twelfth thoracic nerves. Because of the differing anatomic routes, it is obvious that neurectomy in the interiliac trigone, although, as a rule, it relieves pain which originates in the uterus, will have no effect on pain which originates in the ovaries.

RECEPTION OF PAIN AND CENTRAL TRANSMISSION

Pain is but one of the sensations carried by sensory nerves, but knowledge concerning the manner in which pain impulses are formed is less nearly complete than is that concerning other sensations received from external stimuli (exteroceptive) and concerning those that are received from internal stimuli (proprioceptive).[4] This sensation apparently has its origin in stimulation of free nerve terminations while other types of sensation apparently are caused by stimulation of specific types of end organs such as muscle spindles, organs of Golgi and pacinian corpuscles. There seems to be but little doubt, however, that there are specific nerve endings which respond to appropriate painful stimuli and not to others.[5]

After such a stimulus the pain impulse is carried over nervous pathways to the spinal cord, as has been indicated in the foregoing sections. An important physiologic fact is that neurons which carry each type of sensation separate into groups soon after they have reached the cord. After they have entered the cord through the posterior nerve roots, the sensory fibers which convey the sensation of pain enter the posterior gray column and connect with nerve cells therein. A secondary relay of axons crosses to the opposite side in the anterior portion of the gray matter, to ascend as the lateral spinothalamic tract. The grouping in the spinal cord of axons which convey visceral pain is not as definite as is the grouping of axons which convey somatic pain; it is known [3c] that abolition of true visceral pain by cordotomy requires more extensive section than is required for abolition of somatic pain. After the axons have ascended in the cord to the medulla as the spinothalamic tract they enter the mesial fillet and continue in this structure to reach the thalamus.

The thalamus represents the highest sensory level of lower animals. In man this function is largely taken over by the sensory cortex. As far as the thalamus and consciousness of pain are concerned, it is known that if the connections between the thalamus and sensory cortex are severed, either painful or pleasurable stimuli can be felt and that such sensations are greatly accentuated in degree. From the thalamus sensory stimuli are carried to the parietal cortex, to end, presumably, in the ascending parietal convolution which lies posterior to the central rolandic sulcus.

COMMENT

Interpretation of a stimulus such as pain demands consideration of its severity, duration, location and quality. It is well known that pain which arises in superficial somatic structures can be adequately evaluated as to these characteristics. Cutaneous pain is always of the same quality, no matter what the reason for it may be, and is not difficult of localization.[6] Pain which arises in muscle is more likely to be disagreeable and fluctuating and more difficult to locate. When one endeavors to identify the localé of pain which arises in deeper structures, difficulty arises and it is necessary to take into consideration the mechanism of direct and referred pain.

[6] Lewis, T.: Suggestions Relating to the Study of Somatic Pain, Brit. M. J. **1**: 324-325 (Feb. 12) 1938.

Studies and clinical observations concerning visceral pain form a most interesting chapter in medical history. Ross,[7] Lennander,[8] Head,[9] Mackenzie,[10] Hurst,[11] Morley,[12] Lewis[13] and Kellgren[14] and others have developed more or less controversial ideas relative to the derivation of pain from a viscus. Early authors rejected the idea that pain could arise directly from a viscus. At present, however, most authorities accept two types of visceral pain, direct pain and referred pain. It has been suggested that the viscera have not developed a sense of localization such as that of the skin, so that the effect of disturbance may not be felt in the organ affected. The stimulus may be conducted to that portion of the spinal cord from which the sympathetic nerves that supply the organ are given off and irritability may be set up in that segment of the cord. From there, the stimuli may be distributed as pain or discomfort to somatic regions served by the segment of the cord concerned.

It is highly possible that there is a subliminal fringe, or subthreshold, of excitation of sensory nerves;[15] that is, a certain minimal number of afferent impulses must be received by a central neuron before sufficient excitation occurs to transmit a stimulus to the sensory cortex. For example, afferent sensory impulses are received from a viscus and from a neighboring somatic region, either of which alone is subthreshold, but as these impulses reach the same portion of the cord, the stimulus is sufficient to cross the threshold and a sensory impulse is set up, which is consciously localized in the somatic rather than in the visceral region.

It appears that a certain type of stimulus must be present to produce direct visceral pain. Viscera are insensitive to such stimuli as cutting, burning and crushing but are sensitive to adequate stimuli which threaten to interrupt ordinary physiologic processes. Such stimuli are rapid distention or vigorous contraction of hollow viscera, rapid stretching of the capsule of a solid viscus, crushing or stretching of blood vessels and anoxemia of functioning muscular tissue.

"Even with combined reflex and direct sympathetic nerve response to pain, the pelvic organs remain relatively insensitive to pain."[16] Much of the sensation of pain from visceral lesions is owing to the somatic pain produced by stretching, injury or inflammation of the peritoneum. In diagnosis of the cause of pelvic pain and evaluation of its degree, intangible factors as well as pathologic changes in the viscera must be considered. For example, the pain caused by a lesion of a pelvic viscus may be localized at first, but if the patient becomes anemic, is exhausted by disease or is under nervous or mental stress a subthreshold stimulus, which ordinarily would be unnoticed is registered as pain. Or the stimulus may become of a more generalized nature, until finally the pain or discomfort may have no apparent relation to the affected organ. In certain cases of pelvic pain—for example, certain cases in which the complaint is of so-called uterine or ovarian pain—the sensation perhaps is psychic or psychosomatic in origin. Violent emotion accompanied by vascular contraction of surface vessels and of the vessels of internal organs may give rise to sensations of pain.

ABSTRACT OF DISCUSSION

Dr. Arthur H. Curtis, Chicago: As Drs. Wilson and Mussey have stated, the spinal nerves supply the somatic tissues. The visceral innervation has been considered largely autonomic, comprised of sympathetic and parasympathetic fibers; but it is now believed that an indeterminate number of pain-conducting fibers of sensory nerves are incorporated with the autonomic nerves. The fibers of the superior hypogastric plexus, or so-called presacral nerve, of so much interest in clinical gynecology, are supported in a loosely woven delicate meshwork of connective tissue. One cannot remove the connective tissue in its entirety without destruction of the delicate strands of nerve fibers, many of which are grossly discernible, although more clearly seen with a dissecting lens. I believe that skilled dissection of a well preserved body always reveals innumerable presacral nerve fibers; discovery of a single strand bespeaks inadequate dissection of a desiccated, poorly preserved specimen. It is of surgical interest to note that the nerve trunks of the superior and middle hypogastric plexuses tend to be located to the left of the midline. Presacral neurectomy should therefore be particularly thorough on the left side, which is more difficult to dissect; the superior hemorrhoidal artery and vein and the left ureter should be identified as a routine measure for safety.

Dr. J. V. Meigs, Boston: Drs. Wilson and Mussey's paper is very technical and it is difficult to use its perfect neurologic descriptions in the interpretation of clinical disorders. Certain considerations that I consider important are the interpretation of the pain which occurs in patients suffering with dysmenorrhea. It is extremely difficult to separate real pain from psychic pain, or that which is expected to occur when bleeding appears. To obviate this problem and to indicate to the surgeon which patients may and which patients may not benefit by a presacral neurectomy or excision of the superior hypogastric ganglion a simple test has been developed. This test has been satisfactory in 85 to 90 per cent or more of the patients who have been operated on for relief of dysmenorrhea. Many patients are so conscious of pelvic pain at the time of the menses that a way had to be developed to enable the physician to differentiate real and psychic pain. Sturgis and Albright and later Sturgis and Meigs proved that essential dysmenorrhea could be overcome by the proper use of diethylstilbestrol or estradiol dipropionate. These hormones given in proper dosage prevent ovulation, and it is well known that anovulatory cycles are without pain. This appears to be a good test to separate real dysmenorrhea from assumed or psychic dysmenorrhea. Therefore, before a presacral neurectomy is done one of the methods already described is used to prevent ovulation. I have as a rule used diethylstilbestrol as an oral medicament. The plan is as follows: Starting on the first day of the menstrual cycle the patient is given 1 mg. of diethylstilbestrol for twenty days, and if a flow occurs within three to five days after cessation of the medicament the flow is considered as anovulatory. This flowing should be painless. If the patient says that the pain is just as intense as ever something has gone wrong with her method of treatment. If the patient says that it is the most wonderful treatment and that she had no pain at all, then that patient has true essential dysmenorrhea. If the patient says that she is better or improved but that she still had some pain, then she is suffering from a psychic type of pain and does not evaluate her discomfort accurately. The only patients whom I operate on for pain of dysmenorrhea are those who say, after the use of diethylstilbestrol, that it is wonderful and they had no pain at all. In these patients the results of excision of the superior hypogastric plexus should be 100 per cent satisfactory.

Dr. B. B. Weinstein, New Orleans: I should like to comment on the term "presacral neurectomy" because, as Uncle Remus used to say, "there ain't no such animal." In regard to a prelumbar plexus, the superior hypogastric sympathetic plexus, in the dissection of 300 of these the incidence of a single "nerve" ran slightly more than 1 per cent. I have been interested in this question for some time and have carefully followed the use of superior hypogastric sympathectomy, particularly in primary dysmenorrhea. I think the failures that have been reported in primary dysmenorrhea are based on a lack of appreciation of the anatomy of the plexus and a correct selection of the type of case for which this procedure should be reserved. As Dr. Mussey pointed out, one should be able to differentiate the ovarian and uterine sources of pain, and with the further clarification which Dr. Meigs suggested, one should exercise far more care in the selection of patients as candidates for superior hypogastric sympathectomy. In patients who are properly selected and in those in whom a correct hypogastric sympathectomy is performed, clearing out all the fibers in the interiliac trigone down to the periosteum, there should be universally good results. I should like to call attention to the left lateral deviation of the hypogastric sympathetic fibers in the interiliac trigone, which occasions some of the disappointment in results which have been noted. This deviation of fibers to the left is frequently overlooked, and an area in the midline of the interiliac trigone is excised under the erroneous impression that the so-called presacral nerve has been removed. If one performs a careful resection of the area, removing all the interiliac trigonal fibers, there should be no question about all the nerve filaments being removed and there should also be no question about nerve fibers being found by the pathologist on examination of the excised tissue. Superior hypogastric sympathectomies for primary dysmenorrhea should be reserved as a treatment of last resort, after the more conservative procedures of psychotherapy, adequate sedation, antispasmodics and hormonal therapy have been exhausted.

Dr. John G. P. Cleland, Oregon City, Ore.: Since I was the first, some twenty years ago, to evolve any method of positively determining the nervous connections of any particular internal organ to the cord and was the first to publish after years of experimentation on dogs and private patients conclusive evidence of the sensory supply of the uterus, I may add a little to Dr. Mussey's and Dr. Wilson's presentation of this important subject. May I suggest a test to determine when presacral neurectomy should be done? The pathway of pain from the uterus passes from the presacral nerve laterally upward through each lumbar sympathetic chain to enter the cord by the twelfth and eleventh thoracic roots. The point I wish to bring home is that any one may block the pain of uterine contraction at any point along this pathway of pain. The method I use is based on careful anatomic measurements of the average distances of the pathway from certain constant bony landmarks; so that, whether the patient be thin or fat, the pathway of pain may be consistently blocked with as little as 2.5 to 5 cc. of long-acting anesthetic agent. By the use of such small doses, which have completely relieved pain dozens of times, I feel that I have proved that the pathway does not follow the aortic plexus upward, and that therefore it may be reached, if one so wishes, by the technic of lumbar sympathetic block published by Dr. Alton Ochsner.

Dr. Robert D. Mussey, Rochester, Minn.: I wish to thank the gentlemen who have discussed this paper. I am particularly grateful to Dr. Curtis for his scholarly presentation. In writing this paper we considered that we were distinctly limited to the subject of nervous pathways, and we did not report on some of the avenues which have been discussed this morning. I appreciate the fact that these points have been brought out because the subject of pelvic pain is a broad one and certainly it still needs clarification.

TREATMENT OF CANCER OF THE FACE, MOUTH AND NECK WITH IRRADIATION

CHARLES L. MARTIN, M.D.
and
CARLETON WRIGHT, M.D.
Dallas, Texas

Cancer of the exposed surfaces of the skin and cancer of the mouth are of unusual interest to physicians in the Southern states because of their high incidence in this area. Mountin and Dorn[1] described this geographic peculiarity in 1939 and observed that the increase in the number of oral lesions over that found in other regions was confined almost entirely to women. Although no explanation was offered for this observation, our own experience indicates that it is due to the prevalent habit of snuff dipping among the women of the poorer classes in the South. About 90 per cent of the women admitted to our clinic with cancer of the mucosa of the cheek and palate have dipped snuff for long periods of time.

Phillips[2] called attention to the high incidence of cutaneous cancer in farmers and ranchers in the Southwestern states and reported that 33.8 per cent of 3,683 cancers recorded in a United States Public Health survey made for the Dallas-Fort Worth area in Texas in 1939 were cutaneous lesions. The next highest figure was 30.3 per cent recorded in Birmingham, Ala. Most dermatologists believe that this high incidence results from constant exposure to sunshine and hot winds, which produce multiple precancerous lesions in the blond type of skin found so predominantly in the white population of the Southwestern states. Malignant lesions of the skin are so common in Texas that the average outdoor worker is prone to disregard them until they become large enough to cause pain or inconvenience.

TECHNIC

In our clinic all the lesions under consideration are treated primarily with irradiation and electrosurgical methods, and patients are referred to a plastic surgeon only when complications appear or when a restoration of destroyed tissue is indicated. Since this plan of procedure is looked on with disfavor in some surgical centers, a report of our results should be of interest.

Epidermoid carcinomas of the skin and lip which measure less than 2 cm. in diameter and show little or no infiltration are treated with superficial roentgen therapy. The treatment factors are: 85 kilovolts, 5 milliamperes and a target skin distance of 16 cm. and a filter of 0.5 mm. of aluminum. The area treated must cover the lesion and an appreciable margin of normal skin around its edges. Daily doses of 1,100 r (measured in air) are given for four or five days, the total dose being 4,400 to 5,500 r. When the tumor is elevated well above the surface the presenting portion is removed by electrosurgical intervention with the patient under local anesthesia before the roentgen therapy is started. This procedure is important because it renders the extremely large doses of irradiation recommended by some radiologists unnecessary. A rather severe reaction appears about seven days after the treatment is completed, and the treated area is often

[2] Phillips, C.: The Relationship Between Skin Cancer and Occupation in Texas, Texas State J. Med. **36**: 613, 1941.

denuded. All evidence of the tumor disappears during the period of reaction, and healing occurs in six to eight weeks. The resultant scarring is slight and the cosmetic results, particularly on the lip, are excellent. Each treatment requires only a few minutes for its administration, and the patient loses little time from his occupation. This technic, which has been described in detail in previous articles,[3] was built around the procedure described by Pusey[4] in 1907 and can hardly be looked on as new or untried.

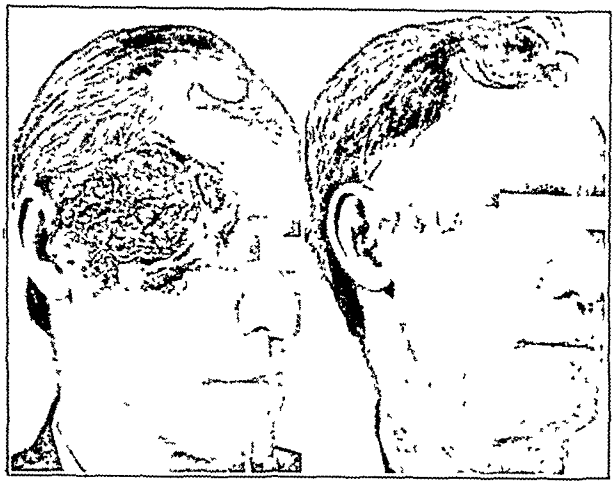

Fig 1.—Large squamous cell carcinoma, grade 2, which has remained well for ten years following one course of roentgenologic therapy given with the Coutard technic

When the superficial method is applied to large areas, the reaction is severe and healing is often slow. Although it was used with some success in the treatment of large lesions in our earlier work, the divided dose deep therapy technic first described in this country by Coutard[5] in 1932 was found to offer many advantages. Our modification[6] of the Coutard method for the treatment of large carcinomas of the skin was published in 1935, but some changes in this technic have since been made. At the present time the treatment factors are: 200 kilovolts, 20 to 25 milliamperes, a target skin distance of 50 cm. and filters varying from 0.5 mm. of copper and 1 mm. of aluminum to 0.8 mm. of tin, 0.25 mm. of copper and 1 mm. of aluminum. The heavy filtration is used when it seems advisable to reduce the cutaneous reaction to a minimum.* Ports measuring 15 cm. on a side have been used successfully, but most of this work has been done through 10 cm. ports. Just as with the superficial method, the area treated must include a strip of normal skin completely surrounding the tumor. For squamous cell carcinoma a daily dose of 300 r measured in air is administered (skipping Sundays) until a total of 3,600 roentgens has been given. The sequence of events is similar to that observed with the superficial technic, but healing may not be complete for two or three months after the treatment is finished. Here again it is desirable to remove polypoid masses by an electrosurgical procedure before the roentgen therapy is started.

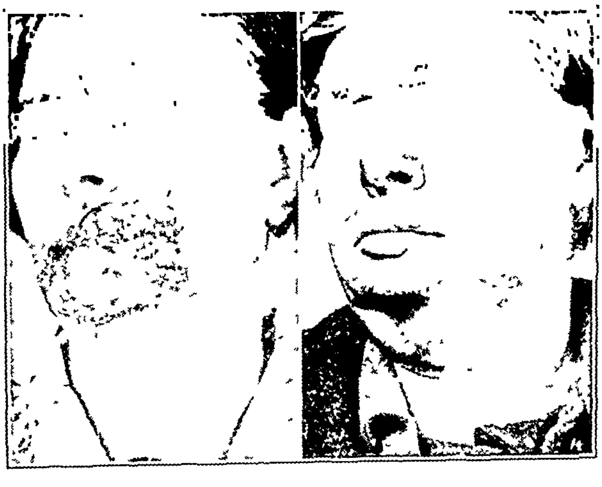

Fig. 2.—Large squamous cell carcinoma, grade 1, which has remained well for ten years following a course of Coutard therapy supplemented by radium needles used in the corner of the mouth and inner cheek.

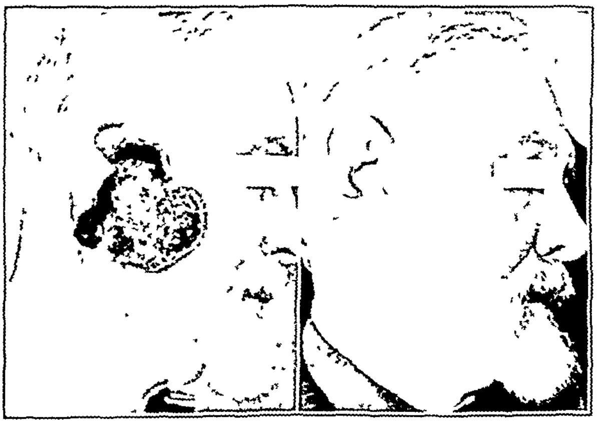

Fig 3.—Large squamous cell carcinoma, grade 2, with involvement of the lower ear which has remained well for five years following the layer radium needle technic.

Although Richards,[7] Hayes Martin[8] and others use the Coutard roentgenologic technic successfully in treating certain intraoral cancers with roentgen rays, we prefer an interstitial radium needle technic for all lesions in the mouth. It is also useful in the care of deep seated lesions on the face and lip. Our needles are patterned after those used by Cade[9] and his associates in England. They contain approximately 0.6 mg. of radium per centimeter of active length, are made of platinum and have a wall thickness of 0.5 to 0.6 mm. The needles found most useful have active lengths of 0.5, 1.5 and 4 cm. In order that dosage may be easily estimated they are always left in place for exactly seven days. With the exception of rounded tumors in the body of the tongue and large masses of lymph nodes, practically all the carcinomas considered in this paper either grow as flat tumors or can be reduced to such layers by electrosurgical means. Treatment is administered by inserting the needles into the base of the layer of growing tissue in patterns designed to deliver not less than 6,000 r to all the tumor cells.

[9] Cade, S.: *Malignant Disease and Its Treatment by Radium,* Bristol, John Wright & Sons, Ltd, 1940.

A diagram which was worked out with the aid of Quimby and published in a previous paper[10] makes the estimation of dosage at various points in the tumor relatively simple. Rounded tumors are treated by inserting the needles in two or more theoretic layers placed one above another. With such a plan the only variable is the arrangement of the needles, and the experienced operator can devise patterns which will effectively irradiate tumors of all shapes and sizes.

In our earlier work, radon seeds could not be obtained and it was found necessary to devise needle technics as a substitute. We were soon convinced that the needles offered certain advantages, which were described in a paper[11] published in 1932. No radon implants are used at the present time.

REACTIONS TO TREATMENT

Too much emphasis cannot be placed on the fact that a rather severe reaction always follows the proper use of a carcinolytic dose of x-rays or radium. This reaction, which consists in a pronounced erythema on the skin and a grayish discoloration in the mucous membranes of the mouth, appears in a week or ten days after the treatment is finished. It is not particularly painful and should not be confused with the extremely painful indolent ulcer which may result from high dosage or improper technics. When large areas are treated the epithelium on intact surfaces disappears soon after the reaction reaches its peak, and it is during this period that the neoplastic tissue rapidly melts away. Healing requires from six to eight weeks or even longer, depending on the size of the lesion. It is our custom to apply dressings of boric acid ointment to the external areas each day. Although we are familiar with the warnings issued against the use of this medicament on denuded surfaces, we have observed no ill effects following its application over long periods of time and we are impressed with the comfort which it affords the patients. Treatment reactions on the mucous surfaces of the lips are more painful than those on the skin, and the frequent application of metycaine hydrochloride ointment 5 per cent gives much relief. Reactions inside the mouth are treated with the frequent use of alkaline mouth washes and the application of a 5 per cent solution of merbromin to the affected region after each feeding.

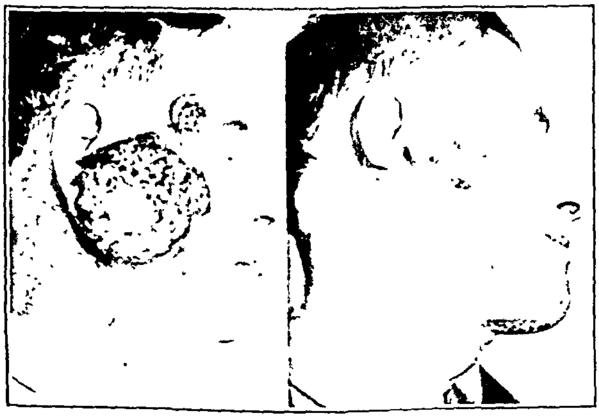

Fig. 4.—Large mixed squamous and basal cell carcinoma with extensive subcutaneous infiltration which has remained well for three years following the layer radium needle technic. The deep scar on the cheek followed coagulation of a recurrent nodule.

The radiologist who is conscientious in his efforts to deliver a carcinolytic dose to every tumor treated will encounter a few cases in which the reaction does not heal promptly but produces a slough instead. Although such sequelae are usually attributed to errors in technic, some of them are undoubtedly due to other factors, such as poor blood supply, excessive fibrosis and previous types of therapy. Superficial sloughs on the cutaneous surfaces respond well to vitamin A and D ointment or cod liver oil ointment used over a long period of time. Sloughs in the tongue or cheek and devitalized areas in the jaw which do not separate after several months of palliative therapy should be removed surgically. Small areas of necrosis in the mouth often result from low grade infections and may be efficiently treated with penicillin lozenges, which not only induce healing but may produce immediate relief of discomfort. Large doses of irradiation applied to the ear or nose may produce an extremely painful chondritis, the discomfort of which is promptly relieved by removal of the involved cartilage.

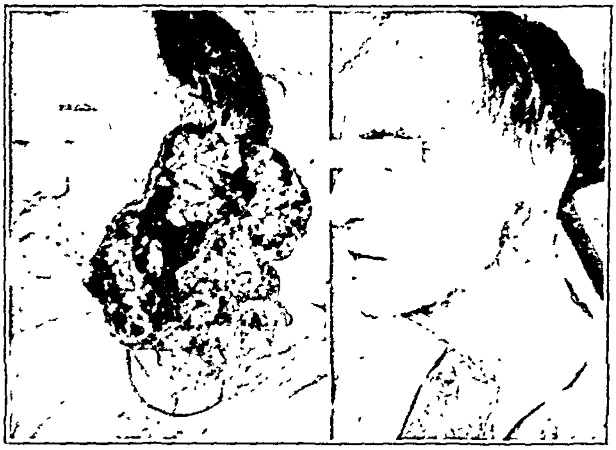

Fig. 5.—Large squamous cell carcinoma, grade 4, which was treated by electrosurgical means plus the Coutard technic. The neck was smoothly healed when the patient died of pulmonary metastases eight months later.

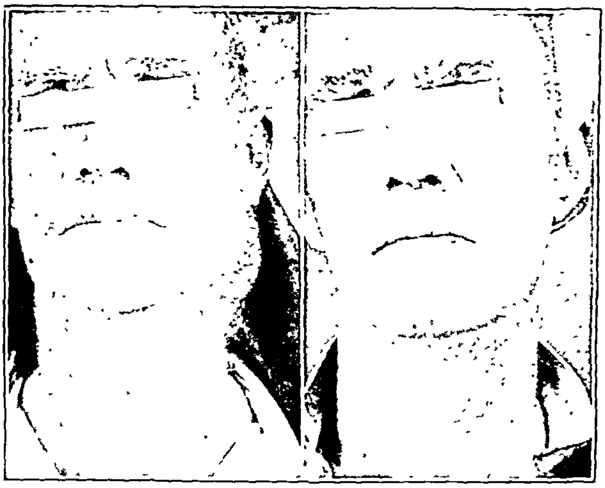

Fig. 6.—Large mass of squamous cell carcinoma in upper cervical nodes diagnosed by needle biopsy which has remained well for six years following the combined radium needle and Coutard technic.

REPETITION OF TREATMENT

The radiologist charged with the care of a cancer patient should make an all-out effort to produce a cure with his first series of treatments because the second attempt is never very effective and may actually produce harmful results. If cures are to be produced the bold application of an efficient technic is preferable to a cautious approach, even though a few untoward sequelae may result. The patient with cancer of the skin who has received relatively small doses of roentgen rays given once a week over long periods of time by the "watch and wait" method constitutes one of our most difficult problems. In these cases the tumor bed has been damaged so that the normal tissues may not be able to recover from carcinolytic doses. When small malignant nodules persist or small recurrences are observed later in heavily irradiated areas it is our custom to remove them by electrosurgical intervention unless the normal tissues are in unusually good condition. When surgical procedures are contraindicated and heavy irradiation is applied a second time as a lifesaving procedure, a slough often results.

CANCER OF THE SKIN OF THE FACE AND NECK

Carcinomas of the skin of the forehead, temples, cheeks and neck, regardless of their size or histologic structure, may be treated successfully with irradiation.

Table 1.—*Proved Advanced Cancer of Face and Lip, 1936 to 1943*

Site	Total No. of Cases	Cases Traced	Living and Well (Yrs.) 10	8	7	6	5	4	3	Well 3 or More Yrs.
Ear..............	19	12	..	..	..	..	..	1	4	5
Face and neck....	44	21	1	..	..	..	3	1	5	10
Lip..............	56	33	2	3	3	1	..	2	3	14
	119	66	3	3	3	1	3	4	12	29

No attempt is made to separate the basal cell and squamous cell lesions, because many of the larger tumors contain cells of both types and it seems best to use technics capable of destroying the most resistant cells which may be encountered in all cases. Tumors measuring less than 2 cm. in diameter are treated by the superficial roentgenologic technic; the large tumors are treated with the Coutard technic if they are fairly superficial and with radium needles if there is much infiltration.

Tumors of the eyelids are treated with the superficial roentgenologic technic. After a topical anesthesia has been produced by placing several drops of a 4 per cent solution of cocaine in the conjunctival sac, a gold-plated brass shield is slipped under the lids. The treatment cone is then placed directly over an opening cut in a piece of lead foil placed so that the tumor and a rim of normal tissue is exposed. With such shielding at the time of each treatment the conjunctiva is not damaged and healing produces a minimum of scarring and deformity. Malignant tumors of the inner canthus may be treated in this manner when they are superficial. However, they frequently are accompanied by deep induration which extends well down into the orbit. This complication is best treated with a layer of weak radium needles with active lengths of 1.5 cm. plunged into the inner portion of the orbit so that they extend well beyond the palpable induration. Cancers of the bulbar conjunctiva respond well to the superficial roentgenologic technic and heal with no demonstrable damage to the eyeball. Two such cases have been followed for eight years, and both patients have good vision. The procedure is the same as that used for the lids, except that an eyelid retractor is inserted at the time of each treatment and the lead foil shield is placed directly over the lesion on the eyeball. The lens must be carefully protected to prevent the formation of a cataract.

Small superficial carcinomas on the nose may be eradicated with the superficial roentgenologic technic, but large lesions, particularly those which invade cartilage, are removed by surgical diathermy. When deep invasion has occurred, the entire nose is removed with the cutting current and the Coutard technic is applied to a circular 7 cm. port which includes the entire nasal passage. After healing has occurred an artificial nose attached to a pair of glasses hides the defect rather effectively.

Carcinoma of the ear presents a similar problem. Although small lesions confined to the skin respond well to the superficial roentgenologic technic, most of the patients coming into our clinic manifest cartilaginous invasion. When the disease is limited to the auricle the involved portion is quickly removed with the cutting current and no attempt is made to approximate the skin edges. For the best results the visible edge of cartilage should be cut away so that the skin edges are in contact. Large carcinomas almost invariably invade the skin in front of or behind the auricle and often undermine this structure. When this complication occurs, the overlying portion of the auricle is removed and radium needles are inserted into the remaining layer of involved tissue on the side of the head. Invasion of the auditory canal is handled by stitching small radium needles into the walls of the passage. In our experience no advanced cancer of the ear has responded well to irradiation without removal of the overlying cartilage, and we consider this procedure an essential part of the technic.

All superficial carcinomas of the lip measuring less than 2 cm. in diameter are treated with the superficial roentgenologic technic, and the cosmetic results are far superior to those obtained with surgical means. Large tumors and those showing deep induration respond extremely well to the layer radium needle technic, and since all normal tissue is salvaged the cosmetic results compare favorably with those obtained by radical surgical intervention. The procedure is simplified by the removal of all proliferating tissue before the implantation is performed.

Although a large number of small cancers of the face and lip have been successfully treated by the technic previously outlined, many of them have not been studied by biopsy and they are not included in the statistical portion of this paper. A series of 119 well advanced, histologically proved carcinomas of the face and lip is reviewed in table 1. All these tumors except a few large basal cell lesions on the face were of the squamous cell variety. The tumors on the face and neck measured from 3 to 9 cm. in diameter, and palpable nodes were detected in 8 of the 44 cases. All 19 cases of carcinoma of the ear showed extension to the skin outside the auricle, and there was a palpable cervical lymph node in 1 case. The tumors of the lip measured from 2 to 5 cm. in diameter, and palpable cervical nodes were present in 17 of the 56 cases. The patients reviewed in this paper come from a floating population, and we have reason to believe that some of those not traced are well. Many of them were old at the time of treatment, and we are fairly certain that some of the deaths were not due to cancer. However, if it be assumed that all the untraced patients are dead, it can still be stated that almost one fourth of the entire number, and nearly half of the patients traced, were living and well at the end of three years

CANCER OF THE MOUTH

It is highly desirable that all teeth situated adjacent to the treatment zone be removed and the gums be healed before irradiation therapy is started

Large carcinomas of the tongue constitute the most formidable problem of all the tumors under consideration. Most of the lesions on the lateral borders and tip can be reduced to flat layers for radium needle implantation by surgical diathermy Masses in the center of the tongue and those situated well back on the root are treated by plunging needles with 1.5 cm. active lengths vertically into the tumors Good exposure is obtained by pulling the tongue well out of the mouth by means of a towel clamp fixed in the tip All needles placed in the mouth must be securely sutured in place. The operator is called on to exercise some ingenuity in devising a pattern which will irradiate all malignant tissue evenly, particularly when irregular extensions are found in the floor of the mouth.

Primary cancers in the floor of the mouth usually are found beneath the anterior portion of the tongue and may extend onto the alveolar margins The best results are obtained by placing a vertical row of the smallest needles along the inner edges of the gums and augmenting them with a few 1.5 cm needles placed transversely under the tumor. Contrary to the general belief, few such cases have shown serious damage to the bone.

Carcinomas of the mucosa of the cheek are usually flat tumors, and they lend themselves naturally to the layer radium needle technic. Extension onto the palate, alveolus and floor of the mouth must be carefully implanted, and each case presents a problem in geometry. The most difficult extensions are those found deep in the cheek just external to the ramus of the mandible and above and outside the upper alveolar margin. Even when all the cancer in this region is eradicated the resulting fibrosis renders complete opening of the mouth impossible, and in a few cases it has been necessary to remove several incisors so that food might be taken in sufficient quantities.

Primary lesions on the anterior part of the pillar and soft palate are always flat and are easily implanted. However, the insertion of needles into the base of a tumor on the hard palate presents a real problem. This procedure is greatly facilitated by injecting a liberal amount of local anesthetic under the membranes beneath the tumor. When the needles are inserted into these edematous membranes they tend to stay in place. Many radiologists prefer contact applicators for such lesions, but some of our implanted tumors have shown good results with the insertion of needles.

After needle implantations are carried out the patterns are studied in roentgenograms of the involved area. Technical errors may be easily corrected by changing the positions of incorrectly placed needles. This checking procedure constitutes a real advantage over radon seed implantations.

A review of 113 cases of well advanced cancer of the mouth is presented in table 2. All the tumors in this series were proved squamous cell carcinomas. The tumors of the tongue measured from 2 to 4 cm. in diameter, and cervical nodes were palpable in 7 of the 36 cases. The lesions on the floor of the mouth measured from 2 to 5 cm. in diameter, and cervical nodes were palpable in 3 of the 12 cases. The lesions on the cheek and palate measured from 2 to 4 cm. in diameter, and cervical nodes were palpable in 8 of the 65 cases. The end results were about the same as those obtained with treatment of the same type of cancer on the face and lip.

METASTATIC CERVICAL LYMPH NODES

All the malignant tumors considered in this paper may metastasize to the cervical lymph nodes, and the care of the neck is an integral part of the treatment. Wilson's[12] recent review of the literature on this subject illustrates the existing diversity of opinion relative to proper therapeutic procedures. Many surgeons are convinced that irradiation produces no cures and that block dissection is the method of choice. A review of published reports indicates that surgical intervention offers a chance of cure in only a limited group of cases with early glandular involvement.

TABLE 2.—*Proved Squamous Cell Carcinoma of Mouth, 1935 to 1943*

Site	Total No. of Cases	Cases Traced	Living and Well (Yrs.) 10	9	7	6	5	4	3	Well 3 or More Yrs.
Tongue........	36	21	..	..	2	..	2	..	3	7
Floor of mouth..	12	10	1	..	1	..	..	2	3	7
Cheek and palate	65	31	1	2	..	4	1	3	4	15
	113	62	2	2	3	4	3	5	10	29

It is true that many of the published irradiation technics are of little value. In our opinion cervical nodes containing squamous cell carcinoma cannot be cured with external irradiation alone because the carcinolytic dose for cancer in lymph nodes is considerably larger than that required for the primary lesion. Although Evans and Griffith[13] have obtained some promising results with implanted radium needles in a few cases, it is our opinion that a combination of interstitial therapy and external irradiation offers a better chance of cure. The combined method is advantageous because the damage to normal tissues is less when part of the dose is given with radium and part with roentgen rays. Hayes Martin[14] has reported 46 cases with proved metastatic cancer in cervical nodes living and well five years after the implantation of radon seeds into the nodes following the external administration of 5,000 to 8,000 r by the Coutard method.

Our own procedure, described in detail in two previous papers,[15] consists in a combination of the layer radium needle technic and the Coutard technic given simultaneously. The doses are large and the reactions rather severe. After healing has occurred the overlying skin may show some atrophy, and a diffuse fibrosis may be felt in the subcutaneous tissues when the treated area is large. In some cases the glands are reduced to hard, fibrosed nodules which remain quiescent, while in others they disappear completely. Patients sometimes complain of mild discomfort in the treated area of the type observed with any large scar, but most of them are quite comfortable. A moderate edema may persist about the treated area for a number of months because of the obstruction of the lymphatics by fibrosis. In a few cases the overlying skin has broken down several years after treatment, but for the most part these complications may be attributed to errors in technic and have been easily remedied by plastic surgery.

Tissue has not been routinely removed from lymph nodes for biopsy, but a study of the 19 cases of proved carcinoma presented in table 3 indicates the effectiveness of the method. Of the 138 cases reported in table 4 palpable nodes were present and treated simultaneously with the proved primary lesion in 58 instances and appeared and were treated after healing of a proved primary lesion in 80. All these nodes were hard and nontender, and many of them were considered inoperable. Only a few glands did not show decided regression after the reaction had subsided. In a few cases with multiple glands treatment was applied to both sides of the neck with a good primary result. The three year salvage of 21 per cent of all the patients treated and almost a third of the traced cases indicates that irradiation of metastatic cervical nodes deserves more consideration than it has been accorded in the past.

PALLIATION

Although the tables included in this paper have been compiled in an effort to illustrate the curative value of irradiation therapy, something should be said of its palliative value as well. It is our custom to give some type of therapy to every patient, regardless of the size or extent of his carcinoma, and the improvement produced cannot be evaluated in a paper dealing with cure rates. Even though these patients may not live three to five years, the eradication of large unsightly tumors and the relief of discomfort by the judicious use of irradiation therapy is still a worth while procedure.

SUMMARY

Cancer of the skin is common in the Southwestern states, where it constitutes approximately 30 per cent of all the malignant lesions treated. The incidence of cancer of the mouth is also high. The absolute three year cure rate in an unselected group of patients with advanced cancer of the face, lip, mouth and cervical nodes treated with irradiation was found to be approximately 25 per cent. The relative three year cure rate in a group of unselected advanced cases was above 40 per cent.

ABSTRACT OF DISCUSSION

Dr. Lyell C. Kinney, San Diego, Calif.: We are indebted to Dr. Martin for the presentation of his method of handling cervical lymph nodes. His absolute cures on a three year basis were 31.5 per cent, and on a five-year basis 26.3 per cent. My associates and I necessarily have had to follow the more traditional and orthodox method of treatment in our work because we have not had the large amount of radium in needles that Dr. Martin has had. In cervical lymph nodes which were small and movable, we have insisted that they be excised or that a radical neck dissection be made. With lymph nodes that were not movable and did not lend themselves to complete excision we proceeded much along Dr. Martin's course. We have given deep therapy followed with implantation of gold seeds. Likewise, in our intraoral work we are not using needles primarily. We are using intraoral roentgen radiation in addition to external radiation, following it where necessary with implantation of gold seeds to bring it up to our estimated dosage. We have found the intraoral roentgen radiation an extremely satisfactory method of handling intraoral cancers, particularly pharynx and tonsillar lesions, those of the cheek and the floor of the mouth. We follow closely Dr. Martin's technic on skin, eyelid and lip, and we have had practically no ocular damage. The important thing in Dr. Martin's paper is the fact that this must be always an all-out attack. No matter what the program is, whether it is a geometrical arrangement of small radium needles plus x-ray, or surgery, the program must be worked out at the onset of the case; the whole of the ammunition must be administered at once, because it is only once that you have the opportunity of treating these patients. We have found it disastrous to try to repeat the radiation therapy or to treat energetically recurrences that have been treated as Dr. Martin has indicated. On the other hand, as Dr. Martin suggests, a small amount of judicial irradiation will prove palliative in certain cases; but there is never another opportunity to cure them.

Dr. Henry Ullmann, Santa Barbara, Calif.: I also see a high percentage of skin and lip cancers in Santa Barbara and I believe the same incidence will be found throughout the Southwest. I have, for many years, been treating with a half value layer of 0.6 mm. of aluminum at a target skin distance of 21 to 22 cm. and lately with a half value layer of 1.6 mm. of aluminum at 14 cm. My total dosage is the same—4,400 to 5,000 r depending on the size of the lesion—divided into two doses a week apart or three doses given every other day. The reaction is usually at its maximum during the second week after the last dose and the area is healed in six to eight weeks. Healing may be occasionally delayed. A mild erythema followed by a slow disappearance of the tumor has been seen several times, as has a complete clearing of the cutaneous reaction in six to eight weeks with the tumor still visible. The tumor disappears eventually, sometimes after a delay of another month. I also use high voltage—a half value layer of 1.15 mm. of copper at a target skin distance of 50 cm. for large lesions. The cosmetic results are excellent. I usually give 4,500 to 5,000 r measured on the skin, as my high voltage dosage is controlled by a "Victoreen Integron III" with the chamber on the skin in the center of the field. I have not used a thorium filter for superficial lesions. I am using gold radon seeds with and without the addition of roentgen rays, but Dr. Martin's results have about persuaded me to get some low intensity needles. Tonsillar and pharyngeal lesions are all treated with the roentgen ray. I should like to ask Dr. Martin how often he sees a late radiation breakdown following these superficial treatments. In cases of mine the incidence has been 3.6 per cent—I am never worried about these breakdowns, as they frequently heal, with less scar than before, in two to three months under a regimen of mild ointments. I use an aloe vera ointment. The breakdown may follow a severe sunburn or other trauma and occurrence is commonest during the second year post radiation. I use this same ointment during the postradiation reaction. I am hesitant about using metycaine hydrochloride ointment 5 per cent because of the number of patients whose skins are sensitive or become sensitive to the prolonged use of this drug. I almost never retreat a superficial lesion with radiation, and I also do not differentiate between a basal or squamous cell lesion in planning dosage. I treat eyelids in the same way but use phenacaine hydrochloride instead of cocaine as it is less drying. I, also, have seen no ocular injury. I should like to ask Dr. Martin how he protects the lens when the conjunctival lesion extends to the limbus.

Dr. Tibor de Cholnoky, New York: As a surgeon I do not agree with Dr. Martin that the operation for cancer is easy and the roentgen therapy is difficult. Both are difficult, and a great deal of thought is required in deciding which to use. The results Dr. Martin has shown are gratifying, although most of his cases were squamous cell cancer of the exuberant variety, which is frequently a local growth, forming metastases late and responding readily to radiation therapy. In the Skin and Cancer Unit of the New York Post-Graduate Medical School and Hospital the number of cases of basal and squamous cell carcinoma treated by irradiation is steadily decreasing, and the preference is for radical surgical excision. A statistical study of 1,062 cases published in the *Annals of Surgery* (**122:**88-101 [July] 1945) emphasizes the usefulness of surgical treatment of cancer of the face. In my experience the carefully executed surgical excision has resulted in better cosmetic results and a higher cure rate, even in more advanced cancer. Although radiation therapy controls some of the basal and squamous cell cancers of the face, the scars and deformities often require corrective surgical intervention. To perform a radical operation followed by reconstruction at the same time is preferable. I was glad to hear Dr. Martin comment favorably on electrocoagulation. It is a useful procedure in the treatment of recurrent and advanced cancer, but only in the hands of a surgeon, for such radical removal of cancerous tissue is often a major operation requiring immediate repair. Basal and squamous cell carcinoma of the skin of the face may be treated alike with wide tridimensional excision, not requiring dissection of the lymph nodes. However, squamous cell carcinoma of the vermilion border of the lip and the mucous membrane as well as that of the ear, with the exception of the protuberant variety, often requires dissection of the regional lymph nodes. Complete dissection of the cervical lymph nodes to prevent recurrence is indicated if the lymph node is involved. This type of dissection is a tedious operation requiring special training. The high percentage of cases which Dr. Martin has just reported as arrested by radiation therapy is a surprise to me. One rarely sees a patient with multiple involvement of the lymph nodes which was proved by biopsy survive five or ten years after radiation therapy. I have seen a large number of failures after radical operative intervention, but I believe that there are more following radiation therapy.

Dr. L. Henry Garland, San Francisco: I should like to ask Dr. Martin to comment on the incidence of pharyngeal contraction, trismus, and so forth, five years after heavy radium and roentgen irradiation around the upper portion of the neck. His percentage of cures in advanced cancer of the ear astounds me: 42 per cent of three year cures! Dr. N. J. Howard recently reviewed the cases of cancer of the ear seen at Stanford and the County Hospital here during the last sixteen years, and he found not only an extremely low percentage of cures, whether operated on or irradiated, but also a high percentage of metastases to the lymph nodes—about 60 per cent of cases, if followed long enough. Some of them developed very late. I should like to ask Dr. Martin in what percentage of his cases of cancer of the skin of the ear metastases to the lymph nodes developed. Will he tell us his incidence of recurrence in treatment of cancer of the skin of the ear with doses of around 4,000 or 6,000 r?

Dr. Charles L. Martin, Dallas, Texas: All the doses of roentgen rays noted in the paper were measured in air. We occasionally see late ulcerations in radiation scars. If they do not respond to the local application of vitamin ointments they are removed surgically. Most of the cancers described in the paper are squamous cell carcinomas, but some of those on the face are of the basal cell variety, and some are mixed. All doses given are large enough to take care of squamous cell lesions. Cancers of the conjunctiva did not extend out over the lens, which was shielded. When the lens is included in the treatment field cataracts usually appear at a later date. It is true that some patients are sensitive to metycaine hydrochloride ointment, but it has been useful in the treatment of temporary painful radiation reactions on the lip. Dr. de Cholnoky's critical discussion is typical of most surgeons' reaction to our work, and I am quite accustomed to it. On the whole our cosmetic results are better than those produced by surgical procedures, and I will be glad to match results with him, scar for scar. His objection to the use of electrosurgery is not well founded, because radiologists were using this method long before it was discovered by the surgeons. My father taught me to use it years ago, and I think we do it rather well. His statement that he has never seen a metastatic cervical lymph node cured by irradiation is surprising, since a sizable number of five year cures in such cases has been reported by the Memorial Hospital in his own city. I hope I may have a chance to show him some of our cases. If they are not cured they have at least remained free of all evidence of the disease for long periods of time. Our treatment of the neck has produced none of the contractions of the pharynx or larynx mentioned by Dr. Garland. Fibrosis of deep seated lesions in the cheek sometimes closes the mouth so tightly that it cannot be opened. No efficient treatment of this complication has been devised in our clinic. I can certainly agree with Dr. Garland's observation that advanced cancer of the ear is poorly treated in most clinics. After growth extends beyond the ear surgical intervention alone has little to offer, and we are enthusiastic about the use of low intensity radium needles plus electrosurgery.

The Gastroenterologic Aspects of Psychosomatic Medicine.—A normal digestive tract cannot have continuous emotional stimuli reach it day after day, week after week, month after month, and even year after year, and still remain normal without showing evidence of physiologic and structural change. We, however, have failed to recognize these changes. Increasing clinical experience, with adequate laboratory and roentgenologic evidence, must show some deviation from the normal if a patient has symptoms. A normal digestive tract, working harmoniously with a normal and nonirritating diet, should give no symptoms. Symptoms arise only as the result of inflammatory and infectious disease, poisons, parasites, neoplastic changes, dietary indiscretions or abnormal nerve impulses. Any gastroenterologist with a broad clinical experience will honestly admit that the majority of his patients have a symptom complex for which no organic basis can be found. We have been much too busy in the laboratory developing diagnostic criteria, making test tube diagnoses, using chemotherapy and antibiotic therapy and forgetting that we are treating a patient who is in a troubled world with its many insults and who is ill because he has a maladjusted emotional household.—Portis, Sidney A.: *Rev. Gastroenterol.*, June 1947.

THYROTOXIC CRISIS

An Analysis of the Thirty-Six Cases Seen at the Massachusetts General Hospital During the Past Twenty-Five Years

JANET W. McARTHUR, M.D.
RULON W. RAWSON, M.D.
J. H. MEANS, M.D.
and
OLIVER COPE, M.D.
Boston

Thyrotoxic crisis ("thyroid storm"), even with improved methods of treating hyperthyroidism, is by no means an extinct phenomenon. Of a total of 2,033 thyrotoxic patients admitted to the wards of the Massachusetts General Hospital in the past twenty-five years, 36 have experienced a toxic crisis. We have thought it worth while to place the analysis of these cases on record since so few[1] of the opinions expressed in the literature of thyroid storm are based on experience with large series of patients.

Twenty-five of these storms (hereinafter called "surgical") have followed the 1,383 operations performed on these patients; the remaining 11 storms (hereinafter called "medical") have represented an acute breakdown of thermal regulation in patients suffering from fulminating thyrotoxicosis. Eight of the medical and 16 of the surgical storms resulted in the death of the patient.

In our view thyroid crisis is not strictly a complication of thyrotoxicosis but an intrinsic feature of the disease. Like ketosis in diabetes mellitus, it is the inevitable denouement of the disease if it be severe enough. Our conception of storm is essentially that it represents the inability of the patient any longer to adjust to the strain imposed by the hyperthyroidism. It might be called decompensated thyrotoxicosis.

We are not in agreement with those who would attempt to draw a fundamental distinction between the medical and the surgical storms. Like diabetic acidosis, storm may be initiated or its onset hastened by intercurrent complicating factors such as infection and trauma (operative or otherwise). Therefore, our definition of storm is a life-endangering augmentation of the symptoms of thryotoxicosis in which the patient's response is out of proportion to the exciting stimulus, whatever its nature (thyroidectomy, pneumonia or wound sepsis). We insert the qualifying adjective "life-endangering" to exclude the mild to moderate febrile reactions which almost invariably follow thyroidectomy in patients whose metabolic rate has not been brought to a normal level. Such reactions differ only quantitatively from the thyroid crisis. They are storms in miniature.

The symptomatology which develops as the denouement is approached depends on the relative vulnerability of the great bodily systems (central nervous system, cardiovascular system and hepatorenal system) subjected to stress by the thyrotoxicosis. The terminal clinical signs and symptoms and the observations at necropsy emphasize a breakdown in one or more of these systems. There are no pathognomonic features common to all cases.

We agree with Buxton[2] that thyroid crisis is a *syndrome* of *many* facets and not a specific entity. Death in this state results from the various complications which are associated with the increased metabolism, and which are often inadequately comprehended and treated.

Table 1 summarizes the number of hospital admissions for thyrotoxicosis, the number of thyroidectomies performed and the number of medical and surgical storms at the Massachusetts General Hospital in the past 25 years.

The season of the year exerted but little influence on the frequency of thyroid crisis. Our data do not support the finding of Crile[3] that storm occurs 2.4 times as commonly during the hot summer months as during the remainder of the year. We have found a rather uniform distribution of crises during the various seasons. If anything, storms have been less frequent during the hot than during the cold months.

Table 1.—*Summary of Data*

Year	Admissions for Thyrotoxicosis	Operation	Surgical Storms	Medical Storms
1921	45	20	0	1
1922	81	48	0	0
1923	75	51	1	0
1924	80	67	1	0
1925	73	55	1	0
1926	68	60	0	0
1927	57	41	0	0
1928	56	53	0	0
1929	72	62	1	0
1930	87	61	1	0
1931	67	54	1	0

1941	108	53	1	0
1942	87	31	2	0
1943	77	36	0	0
1944	74	48	1	2
1945	49	34	0	1
1946			1	1
Total	2,033	1,383	25	11

The age incidence of thyroid storms is shown in table 2. The average age of patients experiencing a medical storm was 49.4 years; that of patients experiencing a surgical storm was 46 years.

Of the 11 medical storms, 1 occurred in a man and 10 in women; of the surgical storms, 8 occurred in men and 17 in women. The 1:3 ratio of males to females experiencing crisis is lower than the ratio for the incidence of the disease in the two sexes.[4] This accords well with the clinical impression that thyrotoxicosis in the male is likely to be severer than that in the female.

Eight of the medical and 12 of the surgical storms occurred in patients with toxic diffuse goiter; 3 of the medical and 13 of the surgical storms in patients with toxic nodular goiter. The relative toxicity of the two types of goiter, as gaged by the basal metabolic rate

on admission and the amount of weight lost, was almost identical. The mortality rates for the storms occurring in patients with diffuse or nodular goiter were likewise almost the same.

The duration of the thyrotoxicosis in patients having a toxic crisis is indicated in table 3. The majority of the storms occurred in patients with thyrotoxicosis of relatively short duration.

The nutritional state of these patients is shown in table 4, which summarizes the amount of weight lost between the time of onset of the thyrotoxicosis and the time of admission to the hospital. The majority of the patients were thin, some so emaciated that they presented the appearance of progressive muscular atrophy. There was surprisingly little evidence of gross vitamin deficiency, except for redness and smoothness of the edges of the tongue in a few cases.

The degree of toxicity may be estimated in another way by considering the basal metabolic rate at entry. Six of the patients with medical storm were too ill to have their metabolic rates determined; the average rate of the remaining five was + 70 per cent. The metabolic rate was not determined in 1 patient in whom a toxic crisis developed after an emergency operative intervention for intestinal obstruction; the average admission rate of the other patients in whom surgical storm developed was + 49 per cent. The frequency distribution for both groups as a whole is shown in table 5. It will be noted that the patients experiencing medical storm were much more toxic than those having surgical storm, both by the criteria of the amount of weight lost and the basal metabolic rate.

TABLE 2.—*Age Incidence of Thyroid Storms*

Medical		Surgical	
Age	No.	Age	No.

The types of therapy received by these patients prior to their admission to the hospital is summarized in table 6. Only 11 of the 36 patients were receiving iodine. All 5 of the previously iodinized patients who had medical storms and 4 of the 6 iodinized patients who had surgical storms were severely toxic at entry despite the iodine therapy.

The incidence of severe complicating diseases and their nature is presented in table 7. Cardiac complications were by far the commonest. Twenty-three of the 36 patients had some type of heart disease, further complicated by congestive failure in 13 instances. That these complications exerted a significant, often decisive, influence on the survival of the patients is clear from table 9, which shows the average age and incidence of serious complicating diseases in survivors and fatalities from storm. Acute toxic psychosis proved to be an ominous sign. Two patients who exhibited this phenomenon preoperatively later died of storm.

TABLE 4.—*Amount of Weight Lost*

Pounds	Number of Patients with Medical Storm	Number of Patients with Surgical Storm
0 to 10	0	4
11 to 20	0	5
21 to 30	1	4
31 to 40	2	4
41 to 50	2	2
51 to 60	1	3
61 to 70	1	0
71 to 80	1	0
Uncertain	3	3

Autopsies were obtained in 12 of the 24 patients who died. The significant pathologic findings are summarized in table 8. Besides the high incidence of cardiac complications, the autopsies revealed the frequency and importance of pulmonary complications. A surprising finding was the paucity of pathologic changes in the liver. We have no doubt that hepatic damage occurs frequently in patients experiencing storm. Foss, Hunt and McMillan, for example, demonstrated central necrosis and fatty degeneration in the livers of 10 of 11 patients who died of thyrotoxic crisis.[5]

TABLE 5.—*Basal Metabolic Rate on Admission*

Basal Metabolic Rate	Number of Medical Storms	Number of Surgical Storms
Not done	6	1

+80 to +89%	2	2
+90 to +99%	..	1

In the majority of instances it was possible to determine a precipitating factor which provoked the crisis in these dangerously depleted patients. These factors are summarized in table 10. In the group of medical storms, iodine withdrawal appeared to be the commonest precipitant of crisis. As has been emphasized before,[4] this phenomenon argues strongly against the concept of "iodine refractoriness." Digitalis intoxication and streptococcic pneumonia progressed rapidly into thyroid crisis in 2 instances.

5. Foss, H. L.; Hunt, H. F., and McMillan, R. M.: The Pathogenesis of Crisis and Death in Hyperthyroidism, J. A. M. A. **113:** 1090-1094 (Sept. 16) 1939.

The majority of surgical storms followed thyroidectomy. These crises were manifest four to sixteen hours (average eight hours) after the operation. Storms blowing up longer than sixteen hours after thyroidectomy proved to be due to bronchopneumonia or wound sepsis. In 3 patients who weathered the immediate postoperative period a crisis developed when hemorrhage requiring secondary suture occurred subsequently.

TABLE 7.—*Incidence of Complicating Disease*

Medical Storms

Bronchial asthma		1
Acute intestinal obstruction		1
Rheumatoid arthritis		1
Acute toxic psychosis		2

As has been indicated earlier, the toxicity of patients in whom medical storm developed was far greater than that of patients with surgical storm. It was therefore difficult to determine the efficacy of any but emergency treatment in the medical group. To study the extent to which the response to hospital treatment influenced the outcome of storm, the data on the patients who had a toxic crisis after surgical intervention has been analyzed separately. Except for 1 thyrotoxic patient who was admitted with acute intestinal obstruction and had a storm following the lysis of adhesions, all these patients were prepared for operation with rest in bed plus either iodine (21 cases) or iodine and thiouracil (2 cases). On these regimens an increase in weight occurred in 10 patients; the weight remained stationary in 2, and 10 actually lost weight. The same trend is reflected in the basal metabolic rates and pulse rates. The way in which the response to treatment affected survival is indicated in table 11.

Subtotal thyroidectomy was performed in 13 instances and hemithyroidectomy in 11. The type of anesthesia employed did not materially affect the postoperative course. The oncoming storm could not be predicted accurately from the intraoperative reaction, although many of these patients showed alarming elevations of pulse rate and blood pressure during the operation.

It is clear from table 11 that there was a significantly greater toxicity in patients who died of postoperative storm than in survivors. Their initial loss of weight was almost three times as great and on admission their basal metabolic rates were higher. Serious complicating diseases were three times as common in the fatal cases. The average gain in weight during the preoperative period in both groups was 2½ pounds (1.1 Kg.); a relatively insignificant increment in the depleted group later to die of storm. The preoperative basal metabolic rate levels were almost identical in the two groups, but the pulse rate was still appreciably elevated preoperatively in those whose storms terminated fatally. The difference in the number of fatalities following hemithyroidectomy and subtotal thyroidectomy is not significant.

TABLE 9.—*Influence of Age and Serious Complicating Diseases on Survival*

	Number	Average Age	Number with Complicating Diseases
Survivors	12	45	5
Fatalities	24	49	19

We have little to add to the classic descriptions of the clinical appearance of patients in thyroid storm. The "activated" type of storm characterized by restlessness progressing to delirium, tachycardia, vomiting and diarrhea, dehydration, jaundice on occasion and a fever rapidly mounting to 106 F. or higher was the commonest variety in our series. Two of our patients presented the classic appearance of the "apathetic" storm characterized by extreme prostration with muscular hypotonia, mental apathy and a temperature rarely exceeding 101 F. It is not apparent from our data on what this profound difference in response to thyrotoxicosis depends.

Patients whose crises were initiated by acute pyogenic infection exhibited the leukocytosis and neutrophilia appropriate to the infection. Those whose storms were provoked by trauma, such as thyroidectomy, had a normal white blood cell count.

The fundamental pathologic physiology of thyroid crisis (or indeed, of hyperthyroidism) being unknown, a complete and rational therapeusis has not yet been devised. The first patient in our series was treated with antipyretics and hypnotics. Iodine has been employed in all subsequent cases together with a variety of adjuvants such as sedatives and oxygen. In the middle thirties the important role of the liver in thyrotoxicosis became appreciated, and intravenous dextrose was added to the therapeutic regimen. Vitamin preparations began to be administered in the late thirties. Our last 4 patients have been treated with both thiouracil and iodine. An initial dose of 0.6 Gm. of thiouracil was followed in one hour by 30 minims (2 cc.) of saturated solution of potassium iodide, and the two medicaments were continued simultaneously thereafter. Our last 3 patients have been treated with supplementary injections of adrenal cortical extract in doses adequate to combat an addisonian crisis. We have had no experience with spinal anesthesia as a mode of treatment. Since the gravity of thyroid storm precludes the performance of a controlled therapeutic experiment, we are unable to subject these data to critical evaluation.

REPORT OF CASES

The following case history of a patient who survived an apathetic storm is reported to illustrate the therapy employed in the most recent crisis which we treated.

Case 1.—A woman aged 29 was admitted to the Massachusetts General Hospital on March 18, 1946, complaining of intractable vomiting and diarrhea of two weeks' duration. She had been having fifteen to twenty bowel movements each day and five to eight at night. She had vomited everything she had eaten. One week prior to admission there developed in the upper part of the abdomen pain which radiated around both costal margins.

She had been extremely nervous during her first pregnancy three years previously and for several months after delivery. The nervousness gradually subsided spontaneously but recurred two years prior to admission, together with fatigue and loss of 25 pounds (11 Kg.) despite a good appetite. She again recovered without treatment and regained her lost weight. One year prior to admission her friends began to comment on the increased prominence of her eyes. Once more she became fatigued and nervous and lost 15 pounds (6.8 Kg.). She experienced episodes of vomiting and diarrhea about once a month, of which the episode leading to hospital admission was the severest.

On admission the temperature was 100.4 F. per rectum, the pulse rate 120, the respiratory rate 24 and the blood pressure 130 systolic and 80 diastolic. There was moderate proptosis of the eyes with lid lag. The thyroid was diffusely enlarged to three times the normal size. The heart was not enlarged. A grade 3 systolic murmur was audible over the entire precordium. The pulmonary second sound was louder than the aortic second sound. There was diffuse tenderness in the epigastrium without spasm. The white blood cell count was 12,700 and the urinalysis revealed normal conditions. An electrocardiogram showed the tachycardia to be of sinus origin. A surgical consultant ruled out an acute condition in the abdomen requiring emergency surgical intervention, and a diagnosis of hyperthyroidism was made. She was given phenobarbital, codeine, acetylsalicylic acid and soluble pentobarbital. When the patient was seen several hours later by a thyroid consultant, she was no longer agitated but extremely apathetic and weak. Her color was gray, and she appeared to be in shock. There was a faint icterus of the scleras. The pulse rate had increased to 180, and the blood pressure had fallen to 100 systolic and 60 diastolic. She was placed in an oxygen tent and given thiouracil 0.4 Gm. immediately and 0.2 Gm. every six hours; 30 drops (2 cc.) of potassium iodide one hour after the first dose of thiouracil; 20 cc. of whole adrenal cortical extract intravenously and 5 cc. every hour intramuscularly. A 250 cc. transfusion of plasma, 600 cc. of a solution of 25 per cent dextrose in water with added vitamins and 750 cc. of isotonic solution of sodium chloride were given during the next twenty-four hours.

Chart 1 (case 1).—Clinical course and treatment employed during apathetic thyroid storm. * Each 1 cc. of vitamin B complex contains: thiamine 20 mg., riboflavin 6 mg., calcium pantothenate 2 mg., pyridoxine 1 mg., nicotinamide 40 mg., choline 10 mg. and para-aminobenzoic acid 5 mg.

Forty-eight hours after admission the patient appeared stronger. Her urinary output, which had been virtually nil since entry, now began to increase. There was unmistakable scleral icterus. The blood pressure, which had fallen to 74 systolic and 50 diastolic, had risen to 110 systolic and 60 diastolic, and the pulse rate had slowed to 148 per minute. There were slightly impaired resonance and decreased breath sounds at the base of both lungs. She was thought to have early bronchopneumonia. The administration of penicillin in a dosage of 24,000 units every three hours was begun intramuscularly and continued for eight days.

Three days after admission the patient became restless, nauseated and slightly distended. She began to pass large amounts of fresh clotted blood rectally and continued to do so for the next twenty-four hours. The blood pressure fell to 100 systolic and 50 diastolic, and the pulse rate rose to 175. She was given two 250 cc. plasma transfusions and six 500 cc. whole blood transfusions during the next five days. Menadione was admin-thiouracil therapy was required to lower the basal metabolic rate from + 45 to + 8 per cent As the basal metabolic rate fell, the patient's course was further complicated by digitalis intoxication and a bronchitis due to Esch coli, which responded to intensive therapy with aerosol penicillin When she was finally operated on four months after entry, she weighed 90 pounds (40 8 Kg) A small multinodular goiter was removed under local anesthesia There was considerable fluctuation in the blood pressure during the operation, but the pulse remained stable No febrile reaction occurred postoperatively, and convalescence was smooth

Many of the articles in the literature of thyroid crisis leave one with the impression that storm is an essentially capricious phenomenon, likely to occur after relatively trivial surgical procedures in patients who exhibit minimal toxicity With this conception we profoundly disagree Storm warnings, often not heeded except in retrospect, were displayed by every one of our patients Thyroid crises occurred in patients with severe thyrotoxicosis who were nutritionally depleted, who suffered from serious complicating diseases and in whom therapy did not accomplish a notable amelioration of the thyrotoxicosis Now that effective medical measures are available, there is no excuse for operating on such patients (except for emergency procedures) until the thyrotoxicosis and its metabolic consequences have been completely neutralized

CONCLUSIONS

1 Thyrotoxic crisis ("thyroid storm") has occurred 36 times in 2,033 thyrotoxic patients admitted to the wards of the Massachusetts General Hospital in the past twenty-five years

2 Two thirds of the 36 patients died

3 Without exception, storms occurred in patients whose thyrotoxicity was great, as indicated by decided loss in weight and a high basal metabolic rate on admission Severe complicating diseases, especially heart disease, were common in thyrotoxic persons in whom a crisis developed These complications exerted a significant influence on the survival of such patients

4 The postmortem findings disclosed the frequent occurrence of cardiac and pulmonary pathologic conditions in patients who died of thyroid storm Surprisingly few patients had any demonstrable hepatic lesions

5 Precipitating factors identifiable as provocative of thyrotoxic crisis included thyroidectomy (14 cases), pneumonia (7), iodine withdrawal (4), postoperative hemorrhage and secondary suture (3), wound sepsis (2) and digitalis intoxication (1)

6 The likelihood of a patient's weathering a postoperative crisis could be predicted accurately in retrospect by his response to preoperative treatment Patients whose thyrotoxic symptoms were not ameliorated preoperatively and who failed to gain weight did not survive thyroid crises

7 The therapy of a patient in storm should be individualized to correct all the recognizable abnormalities stemming from the hypermetabolism, as illustrated by the report of a recent case to show the treatment currently being employed

8 The advent of thiouracil and related goitrogenic agents promises a significant reduction in the incidence of postoperative thyroid storm, once the necessity for continuing the administration of antithyroid drugs until the patient is rendered euthyroid has been grasped.

Clinical Notes, Suggestions and New Instruments

TRIPELENNAMINE "PYRIBENZAMINE" OINTMENT FOR THE RELIEF OF ITCHING

SAMUEL M FEINBERG, M D
and
THEODORE B BERNSTEIN, M D
Chicago

The palliative benefit produced by the oral administration of tripelennamine hydrochloride ("pyribenzamine hydrochloride" N N R) and other antihistaminic drugs on the symptoms of many allergic manifestations has now been fully demonstrated[1] In the dermatoses the effect of these drugs has been to reduce the edema of the lesions, but above all they have been effective in the relief of the pruritus There is some evidence that even pruritus not definitely ascribable to an allergic cause such as pruritus due to icterus or to diabetes, has been relieved by these drugs We have shown also[2] that the local application of a solution of the antihistaminic substance to a scratch on the skin inhibits the normal whealing from histamine or that from an antigen, such as ragweed, in an allergic person We further demonstrated that a solution such as tripelennamine hydrochloride would penetrate the skin when applied to the unbroken integument This was shown by applying the antihistaminic substance to an area of dermographic skin and then stroking this part and the contiguous untreated skin Dermographic whealing took place only at the untreated areas, skipping the treated site We had observed over several seasons a patient with hay fever due to ragweed whose only unrelieved complaint was a pronounced itching and dermatitis of the nasal vestibule and the upper lip During the 1945 season we applied cotton soaked with a solution of an antihistaminic drug to these areas Decided relief and healing of the dermatitis followed

The foregoing considerations led us to hope that topical applications of these drugs might be of value in itching dermatoses, particularly atopic dermatitis Our first preparations were aqueous solutions of the drug, later, mixtures containing vegetable gums were used We decided finally that ointments would allow more prolonged contact Our preliminary crude ointments made by mixing the tripelennamine hydrochloride crystals with the ointment base indicated to us that concentrations above 2 per cent would probably be too irritating, while those far below that strength would not be sufficiently effective The results to be described are based on the use of 2 per cent tripelennamine hydrochloride in both anhydrous and water soluble base

Topical application of 2 per cent tripelennamine hydrochloride in water soluble or anhydrous base ointments was tried in 33 cases of atopic dermatitis (flexural eczema) These patients suffered from varying grades of chronic lichenifying forms of the disease to exceedingly acute states, and the lesions varied from those confined to the antecubital fossae to those of generalized eczema Most of the cases were severe Either prior to the local treatment or subsequently all patients were

studied and observed for allergic factors: the majority disclosed definite cutaneous reactions and observations which indicated relationship between the eczema and specific allergenic causes. Thirteen of the patients were adults, while only 10 were under 10 years of age. The patient was instructed to apply the ointment as often as needed. Twenty-four of these patients reported consistent relief from the use of the ointment. In some instances the continued antipruritic action and the cessation of scratching produced improvement in the inflammation. In some patients who were relieved the results were additive to the benefit obtained by the use of this or other antihistiminic drugs orally: in other words, more complete freedom from itching was obtained by the simultaneous use of internal and local application of the drug. There were a few instances in which the oral or local treatment was the only one effective. The topical application was found to be particularly desirable in patients whose lesions were localized to small areas On a number of occasions while the patient was in the office we were able to demonstrate a striking result in a few minutes by applying the ointment in one area (one arm, for example) and having the patient compare it with other sites. A number of patients volunteered the information that this ointment gave them relief exceeding that obtained from any other topical applications, including local anesthetics. Occasionally the ointment was irritating, particularly when there was acute inflammation. A stinging sensation occurring for a few moments after the application of this medicament is no contraindication to its use.

We also had the opportunity to apply this topical medicament to 9 patients with pruritus ani. Three of these patients had been subjected to allergic studies by us because of a complaint of vasomotor rhinitis. It cannot be said at this time, however, that their anal pruritus was due to allergy The other patients were not studied by us: they were friends of the previous 3 patients and were anxious to try the ointment because of the good results obtained by the others. Eight patients had symptomatic relief, in most of them exceeding the benefit obtained from anything they had used previously over a period of years. In 1 patient, whom we had an opportunity to observe periodically, there was a noticeable diminution in the acuteness of the inflammation.

We also had occasion to note the effect of this medicament on several other types of dermatitis. In 2 cases of contact dermatitis of the eyelids, in 2 of dermatitis of the arms of unknown nature and in 1 case of dermatitis of the legs of unknown cause, improvement in the itching was obtained. In a patient with urticaria the pruritus caused by the individual lesion was relieved by the application of the ointment to the lesion. In 4 other cases of dermatitis no benefit was evident.

The choice of the water soluble base or the anhydrous base would depend somewhat on the individual circumstances. In most instances the water soluble base might be preferable because it appears to be quicker and perhaps more pronounced in activity. The anhydrous base, however, might be preferred when a greasy covering is desired. It should be remembered that this type of treatment does not supplant other internal therapy or allergic management. The allergic approach is of basic importance, particularly in the older age group of atopic dermatitis. Nor does the tripelennamine ointment take the place of other local therapy, such as lotions of solution of aluminum acetate or tar or naphthalan applications. This is a special therapy, which is aimed at relief of the itching and secondarily at inhibition of some of the detrimental effects of the histamine-like substance released in the skin as a result of the allergic reaction. Our preliminary trials indicate that some of the other antihistaminic agents could be used topically in a similar manner.

SUMMARY

Tripelennamine ("pyribenzamine") hydrochloride in a 2 per cent concentration in ointment form applied locally has been found to give relief to the majority of patients with itching dermatoses, particularly atopic dermatitis and pruritus ani.

185 North Wabash Avenue.

Council on Physical Medicine

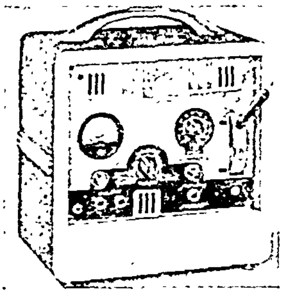
The Council on Physical Medicine has authorized publication of the following report. Howard A. Carter, *Secretary.*

BURDICK MUSCLE STIMULATOR ACCEPTABLE

Manufacturer: The Burdick Corporation, Milton, Wis.

Two currents are provided by the Burdick Muscle Stimulator for therapeutic use. One is designated "galvanic" and the other "stimulator." The galvanic current was tested for percentage of ripple and was found to be almost ripple free—the ripple was too small to be measured. This current is suitable for ion transfer, electrolysis and the stimulation of muscle—denervated and normal—by using an interrupter key to open and close alternately the current circuit.

The current designated "stimulator" is a condenser discharge of small capacity controlled by an interrupter. *It is not a faradic current.* The current is surged by means of a geared mechanism to which a handle is attached for use by the operator. This mechanism is easily controlled and permits the operator to determine manually the rate of muscle contraction as well as the degree. It performs a function similar to the manual manipulation of the "Morton Smart" machine for securing the graduated muscular contractions. This current can be used for stimulation of the muscle having an intact nerve supply. It cannot be used to secure contraction of the partially or totally denervated muscle. Therefore its use is confined solely to treatment of the muscle with an intact nerve supply.



Burdick Muscle Stimulator.

The unit is small, portable, compact and well constructed. The cabinet is of metal and measures 20.3 by 30.5 by 30.5 cm. The unit weighs 12.25 Kg. It is equipped with the usual standard accessories, which are placed in a special compartment at the base of the cabinet. The dispersive pad, 12.7 by 10.2 cm., supplied with the unit tested on patients, was found to limit the current intensity to a maximum of 35 milliamperes without danger of an electrical burn. The unit has a minimum but an adequate number of controls and meters. The ammeter is calibrated from zero to 12 milliamperes for precision readings and from zero to 60 milliamperes for maximum output.

The Council on Physical Medicine voted to include the Burdick Muscle Stimulator in its list of accepted devices.

PLICOSE-WATASEAL PILLOW AND MATTRESS COVERS ACCEPTABLE

Manufacturer: Fine Art Apron Co., Inc., 50 West 29th Street, New York 1.

These pillow and mattress covers are designed to alleviate the distress caused by symptoms of asthma and allergic disturbances due to feather and bedding dust. The pillow and mattress covers are made of a plastic composition known as vinyl film, which is resistant to alcohol, mineral oils, ammonia, iodine and soap. Samples were examined in a clinic acceptable to the Council on Physical Medicine, and the claims for resistance to the several aforementioned agents were verified. The "Plicose-Wataseal" nonallergenic pillow covers were found to be satisfactory for the purpose for which they are intended.

The Council on Physical Medicine voted to accept the "Plicose-Wataseal Pillow and Mattress Covers" for inclusion in its list of accepted devices.

SATURDAY, JULY 5, 1947

BRUCELLOSIS

The erroneous concept still is prevalent that brucellosis is a regressive, rare and self-limited disease. Infection of nonimmune persons must be expected to continue as long as infected food is ingested or there is contact with infected cattle, goats, swine, sheep or horses. Some idea of the importance of the existing problem can be gained from statistics compiled for the state of Iowa, where 638 cases were reported in 1946.[1] Histories obtained in 96 per cent of the cases showed direct contact of the patient with hogs and cows before the recognized onset of the illness in 74 per cent. The remaining 26 per cent were assumed to have contracted the disease through ingestion of unpasteurized dairy products.

The total number of cases reported in the United States has averaged about 4,000 yearly for the past several years. Only the relatively severe acute illnesses are diagnosed and reported. Chronic infections outnumber the acute illness by a ratio of at least 10 to 1 but these chronic infections are rarely diagnosed. If 4,000 cases are reported yearly it is probable that from 40,000 to 100,000 infections occur yearly. If only 40,000 cases occur annually, 400,000 cases will have occurred in a ten year period, with an unknown percentage of this total accumulating from year to year as persistent or recurrent illness.

Although the mortality is usually low, higher rates may occur, especially in the presence of epidemics of the more virulent suis infection carried by raw milk. Cross infection apparently is increasing, allowing the hog or the cow to transmit the virulent melitensis or suis strain to man. In what degree the less severe infections may contribute to death indirectly is unknown.

The annual food loss in milk, butter, beef, veal and pork reaches a staggering total in calories of the kind most needed by an underfed world. The incidence of infection in cattle is still high. Huddleson[2] made estimates for the state of Michigan based on the pooled results of investigations of others. The average infected cow was found to produce about 2,065 pounds less milk per lactation period than the noninfected cow. Estimating that 10 per cent of 1,080,000 cows in the state of Michigan were infected, he considered that the 108,000 infected cows resulted in a total milk loss of 222,904,000 pounds of market milk yearly—enough to supply about 557,000 persons for one year. The loss in butter was translated into about 11,140,200 pounds per year—enough to supply 655,300 persons for a year. Because of abortion or sterility due to Brucella infection a loss of about 16,240 calves per year was estimated, representing a loss of 1,299,200 pounds of veal or of 6,494,000 pounds of beef or a proportionate annual loss in dairy products if calves were raised as milk-producing animals. The true incidence of hog infection is not known, the blood agglutination reaction being even less reliable in hogs than in cattle. It is thought to be relatively high, however. On one hog farm 82 per cent of the expected pig crop, or 54,180 pounds of dressed pork, was lost through infection.

Failure of recognition in a large percentage of chronic cases of brucellosis is to be expected except with the most careful study. The concept has not yet attained general acceptance that brucellosis is no less protean than tuberculosis or syphilis, that it may simulate many other conditions, including psychoneuroses and that it may coexist with any of them. There are no pathognomonic signs and no single uniformly reliable diagnostic procedure. The blood agglutination with Brucella is frequently negative in the acute illness and usually negative in the chronic illness: it has significance only if positive. It is still used as the one single criterion of diagnosis by a majority of practitioners, although positive cultures repeatedly have been demonstrated in the absence of blood agglutinins. The employment of all available laboratory procedures, in addition to the exhaustive clinical study—complete blood counts, sedimentation rates, immune reactions, intradermal tests and culture—may be essential to diagnosis.[3] Rarely is it justifiable to draw conclusions from the intracutaneous reaction alone.

A defeatist attitude toward treatment, not justified by results reported by various methods, also prevails. Development of still better methods in diagnosis, treatment and prevention, in animals and man, depends upon an increasing "brucellosis-mindedness" and continued investigation. The disease continues to be a major public health problem. Pasteurization of all dairy products must remain the greatest bulwark against human infection until methods of control can be perfected.

ENRICHMENT OF CORN PRODUCTS

Consideration of the enrichment of corn products now comes as a logical corollary to the enrichment of white bread and flour launched in May 1941. Corn is a staple human food in the South; in some rural areas it substantially replaces white flour products. Moreover there is a long recognized association of pellagra with diets in which corn predominates. This was attributed for several years entirely to the low niacin content of corn; now it is known that corn also is low in tryptophan, which has come to be recognized as a precursor of niacin. Although milk is low in niacin, its tryptophan content reasonably accounts for the antipellagric effect emphasized by Goldberger. According to Woolley, corn also contains an antiniacin component.

The general adoption of enrichment of corn products has been long delayed principally by the peculiar organization of the industry. National organizations of wheat millers and of bakers warmly welcomed the inauguration of enrichment and did much to promote its general adoption. The corn milling industry, however, is divided into two main branches as far as human consumption of corn is concerned. One branch produces degerminated corn products, largely in the corn belt of the Middle West. Many of these mills are of good size and use well developed and somewhat intricate technologic processes whereby the germ is separately utilized for oil production. Most of the grits and a fair fraction of the corn meal used in the South are of the degerminated variety. The other branch comprises thousands of mills, mostly small, throughout the South which grind the whole grain and market it without separation of the germ. Retention of the germ conserves some of the nutrients, notably thiamine, but niacin is still significantly low. Accordingly each class of product requires quantitatively different additions to attain appropriate and uniform enrichment levels.

The division in the industry has been further aggravated by the adoption of laws in several Southern states which require enrichment of degerminated products but not of whole corn products. This has been justified on the ground that the former is nutritionally more deficient. However, the local whole corn millers are competitive with the Midwestern millers, and they present a difficult enforcement problem because of their numbers and their isolation.

A serious attempt to educate the small miller to enrich his product voluntarily has been under way in South Carolina for three years. Working from Clemson College as a base, Dr. E. J. Lease and his associates have devised an automatic feeder adapted to supply a tiny stream of an enrichment mixture to the corn as it enters a small mill. These feeders have been manufactured by the hundreds. At the same time an enrichment mixture suitable for whole corn products is produced and distributed from Clemson. By this means and with the aid of an agent of the Agricultural Extension Service, about one fourth of South Carolina's 850 millers have been enlisted in the regular enrichment of their product. This project has been aided by substantial grants from the Williams-Waterman Fund for the Combat of Dietary Diseases. Now the effort is being extended into several adjoining Southern states.

Enrichment of corn products will be facilitated by the recent issuance under the Federal Food, Drug and Cosmetic Act of uniform standards of nutrient content for enriched products of corn meal, degerminated corn meal and corn grits. These standards conform substantially to those for enriched white flour. Corn grits present a special problem in that they are customarily rinsed before cooking. However, the nutrients added can be fixed on the particles; means for doing this are now available.

A public awakening to the importance of this campaign is essential for its success. The physician in each community can render a valuable public service by giving the program his support. The general adoption of enrichment of corn products can be expected to eradicate forthright pellagra.

Current Comment

SOME UNUSUAL CASES OF SMALLPOX

The transmission of smallpox usually occurs following direct or indirect contact with a preexisting case. However, cases may develop from unusual sources of infection. Recent experiments by British scientists[1] offer an explanation of some of the unusual methods of transmission of smallpox. In an outbreak in the spring of 1946 in England Downie and Dumbell procured from patients crusts and exudates which they kept under ordinary atmospheric conditions at room temperature. They had also for their experiments crusts from a case in the Middlesex outbreak of 1944 and from 2 cases which occurred in 1945. At intervals a number of crusts were removed from the container, then thoroughly broken up, and sterile buffered distilled water was added. This suspension was left to extract at room temperature for two hours and then overnight in the refrigerator. Next day the suspension was centrifuged, and the supernatant fluid was mixed with penicillin solution to suppress bacterial contaminants before inoculation into fertile hen's eggs. When infection with smallpox virus occurred, characteristic lesions appeared on the chorioallantois in the developing eggs. Experiments were conducted also with smallpox vesicle fluid which had been smeared on glass slides and sent to the laboratory for microscopic examination. In an experiment in which the vesicle fluid was dried in this way the specimen had been taken from a skin lesion in a patient with hemorrhagic smallpox on the seventh day of the disease, one day before the patient died. Virus was found to survive in the diluted vesicle fluid dried on glass slides for thirty-five days when exposed to daylight and for eighty-four days when kept in the dark at room temperature. Smallpox virus was thus recovered from different samples of crusts from patients and kept at room temperature for several months, and from one specimen kept for more than a year. In crusts and dried vesicle fluid kept at room temperature the amount of virus recoverable diminished at first fairly rapidly, but virus was detected many months after this initial period. Virus did not survive as long in the diluted vesicle fluid which had been dried on glass slides as in crusts. There was little relation between the virus content of crusts and the stage of the disease at which they were collected. By the same technic, virus had been isolated from sweepings from the ward floor near a bed in which a child was convalescing from smallpox. These experiments confirm that the material from the skin lesions in smallpox patients is infective. Such material has been responsible for smallpox cases, and smallpox has developed among laundry workers to whom infective material was conveyed on bedclothes. These experiments explain also certain cases in which smallpox has occurred in houses in England to which gifts had been brought from the East. Obviously, therefore, the various articles used by a smallpox patient may long remain capable of transmitting the disease. The skin lesions cannot be regarded as the only source of virus, as patients may spread the infection before their skin lesions develop. A number of people are known [2] to have contracted smallpox after attending the funeral of a patient who died from an unrecognized hemorrhagic attack. The patient's body remains infected for a time after death. Although these uncommon examples are important sources of infection, they should never be allowed to cause the usual human sources of smallpox to be overlooked.

FIBROIDS IN PREGNANCY

Fibroids are sufficiently common during pregnancy to constitute an important complication. Reports of their incidence vary; Buckell,[1] in a review of 122 cases, found an incidence of 0.79 per cent. The average age of Buckell's London group was 34.3 years. More than one fifth of the patients were primigravidas aged 36 or older. Only 79 of the 113 patients who were hospitalized had healthy children. Abortions occurred in 14 per cent and fetal and neonatal deaths in 11.1 per cent. In 57 per cent labor was uncomplicated; cesarean section was performed in 25 per cent of the cases, extraction by forceps in 12.5 per cent and craniotomy once. Uterine inertia was more frequent than in unselected cases but less common than might have been expected. Three of the patients died. One died from postoperative shock following cesarean section, 1 from terminal bronchopneumonia complicated by sloughing fibroids and vesicovaginal fistula after craniotomy and 1 from paralytic ileus three days after myomectomy and cesarean section. Eighty children left the hospital in good health, including one set of twins. Five children were born macerated, 1 was born dead, 2 stillbirths occurred where the cord was pulsating but respiration did not develop and there were 2 neonatal deaths, 1 following premature labor and the other a forceps delivery. Buckell concludes that the presence of fibroids is a serious complication to pregnancy, labor and the puerperium, as it is followed by a high maternal death rate and fetal mortality. Myomectomy during pregnancy, he believes, should be avoided if possible and "red degeneration" should be treated conservatively. A living child can usually be obtained by cesarean section, and this procedure should be seriously considered in all elderly primigravidas and other patients in whom there are additional complications.

EXPERIMENTS ON IMMUNITY TO POLIOMYELITIS

Yale University scientists,[1] members of the Yale Poliomyelitis Study Unit organized in 1931, report results of their immunity studies which provide a better understanding of the mechanics of resistance to infantile paralysis. Eight chimpanzees were given food containing poliomyelitis virus or inoculated with the virus into and under the skin. The animals did not show signs of illness, although almost immediately they began to excrete the virus in their stools; they continued to eliminate virus for as long as five weeks in some instances. Blood tests carried out before the virus was administered, and again after the virus had disappeared from the stools, revealed that specific antibodies capable of neutralizing live poliomyelitis virus had made their appearance in the blood. In some of the animals these antibodies remained present for as long as a year. Some months after Melnick and Horstmann had produced the "intestinal carrier state" the animals were again fed the same strain of poliomyelitis virus or had it injected into and under their skins. The animals now remained resistant to the second attempt at producing an intestinal carrier state. Only when the chimpanzees were given a strain of virus different from the one used to produce the original intestinal carrier state did they again excrete virus in their stools. The results of these studies indicate a relationship between this type of poliomyelitis infection and the presence of specific antibodies in the animals' blood. It may be, the Yale scientists stated, that in these experiments the chimpanzees responded in somewhat the same fashion as do many human beings: they develop a virus intestinal carrier state without signs of acute illness and produce specific antibodies in the blood as the result of this minimal type of infection.

ORGANIZATION SECTION

PROCEEDINGS of the ATLANTIC CITY SESSION

MINUTES OF THE ANNUAL SESSION OF THE HOUSE OF DELEGATES OF THE AMERICAN MEDICAL ASSOCIATION, HELD IN ATLANTIC CITY, JUNE 9-13, 1947

(Concluded from page 806)

HOUSE OF DELEGATES

Fourth Meeting—Thursday Morning, June 12

Roll Call

On motion of Dr. H. B. Everett, Tennessee, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried, the registration slips constituted the roll call.

Presentation of Minutes

It was moved by Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, and carried, that the House dispense with the reading of the minutes.

Report of Reference Committee on Credentials

Dr. G. Henry Mundt, Chairman, reported that 173 delegates had registered.

Report of Reference Committee on Sections and Section Work

Dr. Roy B. Henline, Chairman, presented the following report:

1. Your committee has considered the report of the Council on Scientific Assembly and wishes to express great commendation for the work of this Council. With an unusual amount of effort and with great devotion to their task, they have produced an outstanding scientific program undoubtedly unsurpassed in the history of medical organizations. Your reference committee recommends the adoption of the report of the Council on Scientific Assembly.

2. Resolutions on Sections Celebrating Their Centennials: Your committee received resolutions introduced by Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, the intent of which is to urge the various scientific sections to commemorate their various anniversaries, to give more attention to their social functions and to encourage good fellowship among their individual members. Your reference committee commends this intention and recommends that all sections of the American Medical Association be urged to use every occasion for the promotion of fellowship and for pride in the accomplishment of the particular branch of medicine represented, and further recommends that the Secretary of the American Medical Association send to the secretary of each of the scientific sections a copy of this recommendation.

3. Resolution on Establishment of Section on Diseases of the Chest: Your committee received a resolution introduced by Dr. Walter E. Vest, West Virginia, regarding the establishment of a Section on Diseases of the Chest. The resolution points out that there are about 2,500 physicians engaged in the practice of this specialty; that an enormous amount of progress has been made; that the subject is of enormous import to the American people, and that the general welfare would be served by the establishment of such a section. After hearing from eight Fellows of the Association, who appeared before it, your reference committee is of the opinion that it is advisable to establish such a section, and to that end the committee recommends that section 3 of article 5 of the Constitution be amended by deletion of the figures "175" and the substitution therefor of the figures "176"; and that the By-Laws be amended by adding to section 1 of chapter 15 a newly numbered section, as follows: "No. 19. Section on Diseases of the Chest." The committee further recommends that in the interim the Council on Scientific Assembly allot a portion of the program of the Section on Miscellaneous Topics at the next annual session to the subject of diseases of the chest, and that at that time a section be organized to be known as the Section on Diseases of the Chest.

Respectfully submitted,
Roy B. Henline, Chairman. Lowell S. Goin.
Edgar V. Allen. Scott Lord Smith.
Burt R. Shurly.

The first two sections of the report of the reference committee were adopted on motions of Dr. Henline, duly seconded and carried.

Dr. Henline moved adoption of the third section of the report of the reference committee dealing with the Resolution on Establishment of Section on Diseases of the Chest, and the motion was seconded by Dr. Thomas S. Cullen, Maryland. After discussion and suggestions of amendments, it was moved by Dr. E. Vincent Askey, California, seconded by Dr. Walter E. Vest, West Virginia, and carried, that the House approve a Section on Diseases of the Chest as a section of the Association.

Dr. Askey then moved that this be referred to the Committee to Study Revision of the Constitution and By-Laws so that that committee may take appropriate steps to see that the new section has the proper representation in the House of Delegates, and the motion was seconded by several and carried.

On motion of Dr. Henline, seconded by several and carried, the report of the reference committee as amended was adopted as a whole.

Introduction of Invited Foreign Guest

Dr. Victor Johnson, Secretary of the Council on Medical Education and Hospitals, presented Professor C. Heymans of the University of Ghent, Belgium, who addressed the House as follows:

I just would like to say how glad I am to have this opportunity to join this splendid meeting of the American Medical Association and I consider it as a very great honor indeed. I am also very glad to have this opportunity to express very sincerely my appreciation and very deep appreciation for the splendid achievements made in medical science by different American schools and departments in the different universities and by this American Medical Association. I thank you very sincerely.

Report of Reference Committee on Medical Education

Dr. George W. Kosmak, Chairman, presented the following report, which was adopted on motion of Dr. Kosmak, seconded by Dr. James R. Reuling, New York, and carried:

Resolution on Nursing Shortage: Your reference committee listened to several individuals appearing before the committee to discuss the recommendations incorporated into this resolution. It is impressed with the necessity of considering seriously the question of stimulating the training of nursing personnel in some category of nursing service requiring less time and training while still preserving a reasonably good quality of training to insure satisfactory hospital care. Your reference committee believes that the entire problem of supply and training of nurses requires immediate study. It concurs with the recommendations of this resolution requesting the Board of Trustees to take appropriate action In recommending the adoption of this resolution with a single change in wording, namely that the term "approved hospital" be changed to read "hospital registered by the American Medical Association," your reference committee wishes also to call to the attention of this House that there was adopted yesterday the following recommendation from the Reference Committee on Reports of Officers:

"Your committee recognizes this serious situation It feels that in recent years too much stress has been laid on the technical and scientific preparation for the prospective student nurse rather than on her sympathetic understanding of the problem of patient handling, comfort and ordinary technics of treatment. It recommends that the President appoint a committee of five to be known as the Committee on Nursing Problems This committee shall investigate the present objectives of the nursing profession, the standards of education, the time involved for training, the various curriculums, the supply of nurses and quality of services rendered, remuneration, participation in the determination of administrative policies and the question of security benefits, and to study the training of practical nurses" In recommending the adoption of the resolution under consideration, your committee feels that the House will be acting consistently with the action taken on the recommendation just quoted Your committee recommends adoption of this resolution on the training of nurses and of some category of practical or certified nurse with the amendment quoted.

Respectfully submitted,

George W. Kosmak,
Chairman.
Joseph D. McCarthy.
Thomas S. Cullen.
William D Stovall.
A. W. Adson.

Report of Reference Committee on Legislation and Public Relations

Dr. Thomas P. Murdock, Chairman, presented the following report, which on motions of Dr. Murdock, duly seconded and carried, was adopted section by section and as a whole:

1. Resolutions on Health of the Nation· Your reference committee carefully reviewed these resolutions presented by Dr. T. D Cunningham, Colorado, and recommends their disapproval.

2. Resolutions on Effective Program of Public Relations and Resolution on Establishment of Committee on Public Relations: Your reference committee has reconsidered these resolutions and recommends substitute resolutions, as follows:

Whereas, The House of Delegates has authorized and endorsed an effective program of public relations for the American medical profession, and

Whereas, The American Medical Association is the only organization which is qualified to speak with authority for American medicine, and

Whereas, A major vacancy exists in the recently established public relations organization at the headquarters office; therefore be it

Resolved, That the Board of Trustees set up whatever machinery may be necessary to reestablish this bureau, and be it further

Resolved, That the Executive Committee of the Board of Trustees be in charge of public relations until the bureau is reestablished

3. Resolutions on Support of the SOS Collection of the Joint Distribution Committee. Your reference committee has reviewed the resolutions relative to the SOS (Supplies for Overseas Survivors) and recommends that the resolutions be disapproved for lack of sufficient information.

4 Resolutions on S. 140: Your reference committee has reconsidered the resolutions on the Taft-Fulbright bill and presents the following substitute resolutions:

Whereas, Senate Bill 140, sponsored by Senators Taft and Fulbright, creating a Department of Health, Education and Security has been favorably reported by the Senate Committee on Expenditures in the Executive Department, and

Whereas, The American Medical Association has repeatedly advocated a National Department of Health with a Secretary of Cabinet rank; be it therefore

Resolved, That the House of Delegates go on record as opposing that portion or portions of the bill tying in education and security with health; and be it further

Resolved, That if it is impracticable at the present time to establish an independent Executive Department of Health, the House of Delegates prefers the establishment of a National Health Agency such as proposed in S 545 (also sponsored by Senator Taft and other colleagues) than an Executive Department in which health, education and security activities would be combined

Respectfully submitted,

Thomas P. Murdock,
Chairman.
Thomas A. McGoldrick.
William M Skipp.
Lloyd Noland.
Forrest J. Pinkerton.

Report of Reference Committee on Hygiene and Public Health

Dr Walter E. Vest, Chairman, presented the following report, which was adopted on motion of Dr Vest, seconded by Dr Thomas M. D'Angelo, New York, and carried:

Resolution on National Health Policy· Your Reference Committee on Hygiene and Public Health has reconsidered this resolution, which is apparently the plan now operating in Monmouth County, N. J., for the medical care of the indigent. It embodies ten principles which the New Jersey delegation has found of value in meeting their problems. After study, your committee has revised this resolution to read as follows:

Whereas, The American Medical Association recognizes the need of supplying the professional and administrative leadership at the local level necessary to furnish public health services and adequate medical care to the people of the nation therefore be it

Resolved, That the following principles be promulgated under the leadership of the Board of Trustees or appropriate Council as guide posts to local societies in developing plans for care of the indigent:

1 Each component society will appoint the necessary committees to study the public health and medical care problems concerned and to supervise projects relevant to these problems

2 Each component society pledges itself to maintain a high standard of professional skills among the medical personnel assigned to these projects and to supervise such activities with a view toward maintaining high scientific standards and preventing personal exploitation

3 Each component society invites and welcomes at its discretion the active participation in its scientific programs by the qualified medical personnel of the appropriate health and welfare agencies, and, under suitable circumstances, of the desirable nonmedical personnel as well.

4 The health and welfare agencies will render genuine cooperation with each component society in the implementation of these projects

5 The health and welfare agencies will select their part time medical personnel from lists furnished by, or with the approval of, each component society

6 The health and welfare agencies will clear through each component society any grievances concerning medical personnel

7. The health and welfare agencies will protect the private practitioner and family doctor by discouraging treatment in preventive clinics and by returning to the family doctor any cases not economically suitable for examination or care at the health or welfare agency.

8 The health and welfare agencies will not profit financially by the labors of any medical personnel working there.

9 Each component society and the health and welfare agencies will seek the cooperation of dental, nursing and pharmaceutical organizations in a program fashioned to accord with these principles

10 Each component society and the health and welfare agencies will maintain continuing liaison with one another to implement these principles.

Your committee believes these principles may be of value to the Committee on Rural Medical Service in developing the activities of the rural health councils and may aid in other areas in the evolution of plans for the care of the medically indigent. It therefore recommends that the revised resolution be adopted.

Respectfully submitted,

Walter E. Vest,
Chairman.
James P. Wall.
Walter P. Anderton.
Leonce J. Kosminsky.
James A. Crabtree.

Report of Reference Committee on Reports of Board of Trustees and Secretary

Dr. Elmer Hess, Chairman, presented a report, which was adopted section by section and as a whole as amended. The report as amended reads:

BOARD OF TRUSTEES

1. Resignation of President-Elect: Your reference Committee notes with regret that Dr. Olin West, because of ill health, was obliged to resign as President-Elect. It wishes to commend the wisdom of the House of Delegates in the selection of a strong Vice President. The committee feels that the office of Vice President is an extremely important one and that no one should ever be selected for this position unless he has every qualification for the presidency.

2. Income and Expenditures: In 1946 the net income of the Association was $106,368.35 as compared to $990,708.81 in 1945. However, the committee realizes that this is due to the necessarily increased expenses of all the departments without an increase in the dues for fellowship This is a very good showing and it must be remembered that the American Medical Association is run for service and not for profit.

3. THE JOURNAL: Your committee has nothing but the highest compliments for THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, truly the greatest medical journal in the world, containing as it does scientific and informative news of vital interest to all medical men. The committee is happy to see the increase in the regular correspondence that THE JOURNAL has with many countries around the globe and it is particularly pleased to know that we now have a regular correspondent at Washington. Your committee notes with regret that THE JOURNAL is obliged, because of lack of paper and other facilities, to reject approximately 80 per cent of the scientific manuscripts that are submitted for publication. It hopes that this condition may be soon corrected. It compliments THE JOURNAL for its continued campaign against nostrums, charlatans, cultists and inferior institutions of education. It is happy to note the very pronounced increase in circulation.

4. Field Service: Under the able editorial leadership of Dr. Morris Fishbein, THE JOURNAL has shown definite progressive improvement, but your committee regrets that the associate editors are not used more often in the field service of the editorial staff. It believes that it is essential to the future welfare of THE JOURNAL and the American Medical Association that capable men, even though unable to speak with the fluency and authoritativeness of the Editor, should at least be trained so that they might approach him in effectiveness. After all, the associate editorship should be the proving ground for the individual who must some day, by necessity, take his place.

5. Special Journals: Your committee has reviewed with satisfaction the increase in the circulation and the number of pages of the special journals which are sponsored by the Association.

6. Hygeia: The admission of the fact that the printing of Hygeia must be transferred from headquarters to an outside company increases our necessity for enlarging the facilities and planning and completing our building program in the very near future. It is hoped that planning for the so-called "temple of medicine" might start immediately and that provision might be made for the rapid growth of the whole Association.

Your reference committee is pleased with the increased circulation of HYGEIA which was obtained from selected fields including physicians, dentists, schools, libraries, nurses and other health teaching groups. In the educational field the high school group study plan was initiated whereby HYGEIA is furnished as an auxiliary text for classroom use at a special rate of 15 cents a copy on school orders for ten or more copies. In a recent survey covering these groups, it was found that each copy of HYGEIA is read by an average of four students and that the magazine is used in classes on public health, physical education, biology, personal hygiene, first aid, physiology and science. Your committee wishes to compliment the 1931 House of Delegates which urged the Woman's Auxiliary of the Association to organize and make one of its chief activities the promotion of the distribution of this journal to parent teacher associations, boards of education, schools and colleges and other groups interested in health education. Out of 600 organized county units of the Auxiliary 90 per cent of the orders came from 25 per cent of the county auxiliaries. Twenty-five per cent showed interest but 50 per cent took no part in this work. An attempt should be made to reactivate all of these inactive units in the promotion of HYGEIA. It is noted that, in 1923, 14,175 subscribers were physicians, while in 1946 only 17,000 were physicians. It is suggested that there are more important places for HYGEIA than in the doctor's waiting room. But we should suggest that physicians be encouraged to subscribe and place HYGEIA in locations where its public relations value would be greater than collecting dust on a waiting room table.

7. American Medical Directory: Your reference committee can well understand why the American Medical Directory has not been issued since 1942. Every effort should be made to have a new issue published as soon as possible when adequate personnel and paper supplies are obtainable.

8. Book Publications: Your reference committee has noted that more and more of the books that were formerly published by the American Medical Association are being transferred to private medical publishers. As this is a comparatively new venture, it should be watched closely. If this procedure succeeds from all angles, it should be continued.

Library: Your reference committee commends the continuation of the library service even though there was a shortage of personnel. Many physicians are not aware of the value of the library, and its use should be encouraged.

QUARTERLY CUMULATIVE INDEX MEDICUS: Your reference committee notes the increased usage of the QUARTERLY CUMULATIVE INDEX MEDICUS and notes with satisfaction that this service is greatly appreciated by the membership.

Order and Mailing Departments: Your reference committee wishes to call attention to the enormous amount of mail handled by this department.

Employment Department: Your reference committee notes with satisfaction the good work being done in this department and urges that it be continued along present lines.

Cooperative Medical Advertising Bureau: Your reference committee congratulates the Bureau on its long years of existence and proved value. Since its reorganization in 1945, this department has continued with greater success.

10. Bureau of Health Education: Your reference committee reviews with pride the unusual accomplishment in the entire field of health education by the Bureau of Health Education. The appointment of Dr. Dean F. Smiley and Fred V. Hein, Ph.D. has added immeasurably to the efficiency of the bureau. This bureau should be enthusiastically supported and its activities constantly broadened. Each medium for the distribution of medical information is continually evaluated. For example, the radio script library has been discontinued in favor of the use of electrical transcriptions. Television is being developed experimentally for the transmission of medical information and to develop technics for the use of medical societies generally. Your reference committee recommends the employment as soon as possible of several field men to represent the American Medical Association before lay groups and county medical societies.

11. Council on Industrial Health: Your reference committee commends the activities of this council in its well rounded program for the improvement of industrial health, its advocacy of better labor-management understanding of health problems, the educational program established for further scientific development and education of these programs and finally its efforts to improve the evaluation and advise on industrial disabilities and workmen's compensation.

12. Bureau of Legal Medicine and Legislation: Your reference committee reemphasizes the position taken by the House of Delegates on many occasions in the past in advocating the creation of a federal department of health at the head of which would be an outstanding doctor of medicine and in which could be centralized all the proper health activities of the federal

government other than those associated with the Army, Navy and Veterans Administration. Your reference committee does not believe such health activities could be centralized and properly carried on in a federal department in which health, education and welfare activities are combined.

S. 545, the so-called Taft bill, as now written approximates a legislative background for the development of a health program for the American people as set forth in the broad national health program of the American Medical Association.

The Hill-Burton Hospital Survey and Construction Act has been passed. While not the intent of the act, nevertheless it harbors an implication that aid to needy states might be made contingent on the adoption by these states of model legislation for licensing of hospitals. The state societies should be constantly alert to this implication. Indiana has already passed legislation, without the knowledge of the state medical society, licensing all hospitals.

H. R. 588, to bring barbiturates within the coverage of the Federal Narcotic Laws, will prevent the easy passage of individuals across state lines for the purchase of drugs where the laws governing these drugs differ.

The Medical Aid Act of 1947, S. 678, the Lodge bill, to enable needy persons to obtain expensive drugs, defining "medical aid" to include "x-ray services" and "drugs for various other infectious diseases," seems too liberal.

S. 475, reintroduced, has the same objections as the previous bill in that it has too much centralization. It would permit labor departments to undertake hygiene activities now being done by federal and state public health agencies.

There are many bills pending at this time in Congress of medical interest, but your reference committee does not believe that special comment is necessary at this time.

13. Bureau of Exhibits: Your reference committee wishes praise the entire Scientific Exhibit and hopes that the Army, Navy and other exhibitors will continue their efforts to maintain in the future the high quality of these exhibits. There are few cities with facilities capable of handling the annual session of the American Medical Association. Your reference committee recommends that great care be exercised in the selection of future meeting places.

14. Bureau of Industrial and Personnel Relations: Your reference committee notes with satisfaction that along with the consistent progress our headquarters office has made in recognizing and solving the scientific, economic, sociologic and legislative problems confronting American medicine there has been a recognition of the obligations of the Association to its employees. It is obvious that the effectiveness of headquarters activities depends on the quality and performance of its employees. The successful operation of our newly established Bureau of Industrial and Personnel Relations, in our opinion, will do much to maintain and to improve the caliber of our employees.

15. Council on Pharmacy and Chemistry: The Council on Pharmacy and Chemistry does more than consider evidence on drugs. It promotes research, undertakes product evaluation, best example of which is seen in development of the seal, undertakes educational campaigns in its field of interest, and provides cooperative assistance with other departments at American Medical Association headquarters and elsewhere. Today the outstanding activities of the Council are its evaluation of drugs, cosmetics and allied preparations and the initiation and encouragement of research through its Therapeutic Research Committee, which provides grants, and its Therapeutic Trials Committee, which brings together individuals who have a new idea and those capable of investigating it. Its usefulness to the medical profession is enhanced by the cooperative relationships that it maintains with other organizations. The Therapeutic Trials Committee, although recently formed, is already participating in several major activities. One of the most important factors of this work is that it now provides a means for mutually interested groups to participate jointly in research study.

The Chemical Laboratory is primarily concerned with the testing of drugs that are submitted to the Council on Pharmacy and Chemistry. The importance of this testing does not lie just in examining the contents but in the establishment of standards whereby the drugs can be controlled. The Laboratory is responsible for creating these standards for a large percentage of drugs that come to its attention. Your reference committee commends the work of this council.

16. The Council on Foods and Nutrition: Your reference committee commends the work of this council. It is somewhat similar to that of the Council on Pharmacy and Chemistry except that it is interested in nutrition. The most important part of its work today is concerned with the preservation of the original ingredients of foods and with the proper restoration of foods from which one or more vital factors may have been removed through processing.

17. The Council on Physical Medicine: During the war the Council on Physical Medicine was much interested in rehabilitation. Today it is able to turn more of its attention to the evaluation of products in a field that is still new and not too well known and the need of clarification supported by education. Among the problems that are of particular concern to the council is the use and danger attendant on atomic energy. More recently the Council on Physical Medicine was charged with a responsibility of aiding the Committee on American Health Resorts. Your reference committee commends the work of this council.

18. The Bureau of Investigation: This bureau contains a wealth of material not generally appreciated and which could provide much help for all physicians and their organized associations. It is the one bureau where information may be had concerning quackery and charlatans. One of its most useful procedures is the assistance it gives to schools, clubs and other lay groups.

19. Division of Therapy and Research: These units of the Division of Therapy and Research provide much of the American Medical Association activities in research, product evaluation and the promotion of national therapeutics. Because the problems of these units are frequently related, it is best for them to be grouped for joint consideration where indicated.

The councils welcome inquiries concerning some 200,000 items on which there is information on file in the Bureau of Investigation. The work of these councils and the bureau have become internationally known and today are serving as a model for similar efforts in countries throughout the world.

At the time of the annual session the work of the councils and the bureau is of special aid to the sections, the Secretary's office and the business department, when new ideas and technics are proposed for presentation at the meeting.

20. Bureau of Information and Committee on Rural Medical Service: Your reference committee is pleased with the enthusiastic work of the Committee on Rural Medical Service but also recognizes some overlapping of effort by the Bureau of Information. The latter bureau may later be discontinued but for the present your committee recommends for efficiency and personnel reasons that both the Bureau of Information and the Committee on Rural Medical Service remain as independent units and that their efforts be coordinated through the Council on Medical Service and that Mrs. Shuler be maintained as the Secretary of the Committee on Rural Medical Service.

21. Conference of County Medical Society Officers—Grass Roots Conference: Your reference committee has received very favorable comments on the first meeting held prior to the opening of the American Medical Association session at Atlantic City. Those in attendance were enthusiastic about the conference. Your reference committee recommends the continuation of the conference.

22. American Red Cross Blood Program: Your reference committee recommends the action taken by the Board of Trustees in approving in principle the Red Cross plan for the establishment of a national blood program with the understanding that the operation should be maintained on a community level with the approval of the county medical societies concerned.

23. National Emergency Medical Service: Your reference committee notes with approval the creation in 1945 of the Committee on National Emergency Medical Service and the supple-

menting action of that committee. It earnestly desires the continuation of the study and planning of this committee.

24. Actions with Reference to Committees: Your reference committee notes with confidence that proper committees have been appointed to study closer relationships between the medical and dental professions and one to serve as liaison between the Veterans Administration and the American Medical Association.

25. Addenda: Your reference committee has reviewed the grants for medical research and approves them.

26. Board of Trustees: Your reference committee recognizes the unselfish devotion of each member of the board of trustees to the principles of the American Medical Association and wishes to inform physicians that the affairs of their Association are in splendid hands. It congratulates the House of Delegates in their selection of men of such integrity and faithfulness to those principles. Our affairs are in good hands.

SUPPLEMENTARY REPORT OF THE BOARD OF TRUSTEES

1. Health Problems of Secretary of Interior: The Board of Trustees, learning that the budget of the Department of the Interior for health work in United States possessions—Alaska, Hawaii, the Virgin Islands, etc.—had been drastically reduced and that the Secretary of the Department would be unable to provide the indigent in those countries with much needed medical service, appointed a committee, consisting of the Executive Committee, the Chairman of the Board, the Secretary and General Manager and the Editor, to confer with him.

At the request of Mr. Krug, Secretary of the Interior, this conference was held in Washington. The suggestion was made and adopted that teams of competent consultants—clinicians, not investigators—from hospitals or similar organizations should be invited to be sent by the Department of the Interior for periods of from two to three weeks to consult with the full time staff of the hospital to which they are assigned on the care of these wards of the government and to conduct clinics for the indigent with a view to providing them with a high grade of medical service.

Mr. Krug appointed the Executive Committee of the Board of Trustees, the Secretary and General Manager and the Editor of The Journal, with his chief assistant, Dr. W. A. Morgan, as an executive, to constitute the committee to select the teams. When a team is ready to embark, Dr. Morgan will notify the staff of the hospital to which it is assigned with a view to having it select enough difficult cases so that the time of the consultants will not be wasted.

Your reference committee heartily approves of this action.

2. World Medical Association: The House of Delegates has been informed of the preliminary meetings preparatory to the formation of a World Medical Association and this matter is included in the report of the Board of Trustees. Dr. E. L. Henderson and Dr. Louis Bauer of the Board of Trustees represented the Association at a preliminary organization meeting in London. Dr. Henderson and Dr. Bauer, together with Dr. Ernest Irons as an observer, have been designated to represent the Association at a meeting to be held later in the year. This would seem to be an opportunity and responsibility of the American Medical Association to assist in the development of a world medical front in meeting problems as they develop in the activities of the World Health Organization and in the divisions of the United States. Your reference committee concurs in this action.

3. A Pan American Medical Federation is in process of development and Dr. Harrison H. Shoulders, Dr. Charles Gordon Heyd and Dr. Austin Smith represented the American Medical Association at a preliminary meeting at Havana last autumn. Pan American nations are looking to the United States and Canada for leadership in medical progress, and this would seem to be a helpful measure in the promotion of higher standards of medical care in the Western Hemisphere. Your reference committee concurs in this action.

4. Liaison Committee with Veterans Administration: The Board of Trustees has appointed a committee to serve as a means of liaison with the Veterans Administration in consideration of frequently developing problems of veterans' medical care. Dr. Herbert H. Bauckus, Buffalo; Dr. Edgar P. McNamee, Cleveland; Dr. H. H. Shoulders, Nashville, Tenn.; Dr. R. L. Sensenich, South Bend, Ind., and Dr. George F. Lull, Chicago, were named to represent the Association. This committee was appointed by the Board of Trustees because of the apparent emergencies so frequently developing. Your reference committee concurs in this action.

5. Resolutions on Insurance Against Loss of Wages During Sickness: Resolutions introduced by Dr. Burgess at San Francisco concerning loss of wages during sickness and the report of the reference committee were referred to the Council on Medical Service. That Council, however, is at a loss to interpret the meaning of the report of the reference committee and the Board of Trustees referred this question to the Judicial Council for interpretation. The Judicial Council has now clarified the meaning of the reference committee's report and the matter has been referred to the Council on Medical Service for study and report to the Board of Trustees. Your reference committee concurs in this action.

6. Woman's Auxiliary: The office of the Woman's Auxiliary of the American Medical Association is now located in the headquarters of the American Medical Association. This should make possible a far more effective coordination of the activities of the Auxiliary and the Association. Your reference committee considers this a good move.

7. Costs of Operation: The costs of operation of the Association have increased very greatly in the last several years. The activities of the Association have been greatly expanded. Operating costs in employment of personnel to carry on these activities are the major items in those increases. However, material costs, especially paper, have increased very greatly. Proposed legislation to increase United States postal rates if enacted would add approximately $89,999 to the annual costs of the Association. The income of the Association is derived from advertising and Journal subscriptions. As the $8 annual subscription price of The Journal is only a minor fraction of the cost of the production of The Journal, it is evident that the activities of the Association are dependent on the advertising. The Board of Trustees found it necessary to make some reduction in the operating budgets in order to avoid going into reserve set up for the safety of already established activities of the Association. This information is to assist the House in the consideration of proposals of new activities that may be presented to the House. Your reference committee considers this an essential factor in any consideration of new activities recommended in the House.

8. Resignation of Mr. Raymond Rich and Mr. Charles Swart: Your reference committee approves the action of the Board of Trustees in accepting the resignations of Mr. Raymond Rich and Mr. Charles Swart.

Respectfully submitted,

Elmer Hess, Chairman.
Thomas F. Thornton.
Allen G. Rice.
Albert A. Gartner.
Theodore H. Harwood.

Report of Reference Committee on Miscellaneous Business

Dr. James Z. Appel, Chairman, presented a report, which, on motions of Dr. Appel, duly seconded and carried, was adopted, after amendment, section by section and as a whole. The report as amended reads:

1. Supplementary Report of the Council on Medical Service: Your committee after careful study of the report of Dr. James R. Miller and his advisory committee which concerns "Planning for the Chronically Ill" agrees with the Council on Medical Service that Dr. Miller and the advisory committee should be commended for this report. It further concurs that Dr. Miller and his committee be authorized to proceed further in investigating and evaluating these problems. It is so impressed with this report that it does not believe the report

should lie hidden in the records of the American Medical Association but suggests to the Council on Medical Service that it be published widely and as a further suggestion believes that the report should not only appear in The Journal of the American Medical Association but also might be used as a basis for articles in Hygeia. It further suggests that copies of the report be forwarded to departments of health and welfare of the states of the Union.

2. Resolution on Preparation and Presentation of Resolutions: In the study of this resolution, your committee finds on page 23 of the Handbook the following: "All reports of committees, resolutions, written notices, etc., must be presented in triplicate . . ." Also in the Constitution and By-Laws it finds under Standing Rules of the House of Delegates the following resolution, adopted at Boston, June 7, 1906: "*Resolved*, That in the future all reports, resolutions, amendments to Constitution and By-Laws, etc., be furnished in duplicate . . ." There appears to be an inconsistency in our present procedure and our standing rules. Your committee appreciates the advantages to be gained by the principles of this resolution and believes they should be approved with the amendment that eight copies be presented at the time a resolution is read rather than six copies as indicated in the resolution. It further recommends that this resolution be an amendment to the Standing Rules of the House of Delegates and replace that portion of the Standing Rules referred to above.

3. Resolution on Listing of Names in Daily Bulletin: The principles involved in this resolution have been enunciated by many of the Fellows of the American Medical Association. Your committee recommends the adoption of the resolution and amends it by adding the words "whenever possible."

4. Resolution on Retired Members of House of Delegates: The principles of this resolution are laudable but are so broad that they become very cumbersome. Your committee is at a loss to see how, if this resolution is adopted, the Secretary of the Association will not be forced, year after year, to send congratulatory letters to living ex members of the House of Delegates. Such letters would become meaningless by their annual recurrence. Your committee therefore recommends that this resolution be not adopted.

5. Resolution on Facilitating Efficiency of Work of House of Delegates: Your reference committee is particularly interested in the provisions of this resolution. Any one who has served on a reference committee has had it brought home to him forcefully. The advantages to be obtained by having the purposes of reports and resolutions enunciated by those who are interested, anything that will stimulate further interest in the deliberations of reference committees is of value. Your committee recommends the adoption of this resolution.

Respectfully submitted,

James Z. Appel, Chairman.
Stephen R. Monteith.
John W. Cline.
Hugh P. Smith.
Edward H. McLean.

Report of Reference Committee on Emergency Medical Service

Dr. C. H. Phifer, Chairman, presented a report, which, on motions of Dr. Phifer, duly seconded and carried, after discussion, was adopted as amended section by section and as a whole. The report as amended reads:

REPORT OF COMMITTEE ON NATIONAL EMERGENCY MEDICAL SERVICE

Your reference committee has reviewed in detail the report of the Committee on National Emergency Medical Service. It desires to commend the committee for the diligence with which it has pursued the tasks assigned it by the Board of Trustees at the direction of the House of Delegates.

1. Your reference committee is greatly impressed by the committee's recommendation for the very urgent need for continuous national planning for emergencies, especially in the fields of medical service, health, sanitation and emergency mobilization as well as the necessity of continuous alert supervision of all developments in these fields. In the opinion of your reference committee the possibility of the new aspects of total warfare and special weapons require that the developments and planning for *medical care be continuous. It is,* furthermore, the opinion of your reference committee that this is a major project before your House of Delegates and that it warrants continuing investigation, study and most careful consideration and planning.

2. Your reference committee concurs in the following recommendations of the Committee on National Emergency Medical Service and recommends their adoption:

(*a*) The President of the United States of America and the Congress should be respectfully urged:
   (1) That in war and in peace the Surgeons General of the armed forces have the authority and responsibility for participation, with commensurate rank and at the level of the Chief of Staff and the Chief of Naval Operations of the armed forces, in all military and naval planning, organization and operations as these relate to medical, health, sanitary and welfare services and for the assignment and utilization of medical and allied personnel at home and abroad.

(*b*) That the Secretary of War and the Secretary of the Navy and such other cabinet officers as may be charged with responsibility for our national defense give consideration to possible civilian requirements in a total war in the planning, location and construction of military hospitals and that they reexamine their organizational tables and other procedures used during World War II in order to avoid (1) the medical overstaffing of units; (2) the wasting of the time of doctors of medicine in the performance of nonprofessional duties; (3) the *removal of an excessive number of doctors of medicine* from civilian hospitals and from civilian practice, and (4) a rather widespread failure to make assignments, determine rank and provide for the rotation of doctors of medicine on the basis of their professional qualifications, experience and age.

(*c*) The American Medical Association should go on record as favoring the creation of a National Emergency Medical Service Administration as a continuing function of government, such administration to consist of representatives of the Advisory Board for Medical Specialties, American College of Physicians, American College of Surgeons, American Dental Association, American Hospital Association, Catholic Hospital Association, Protestant Hospital Association, American Medical Association, American Nurses Association, American Pharmaceutical Association, American Public Health Association, American Veterinary Medical Association and Association of American Medical Colleges.

3. National Emergency Medical Service Administration: This Administration shall be charged with the responsibility at all times (1) for effecting plans for total mobilization of the medical and allied resources of the nation; (2) for the procurement and allotment of medical and allied personnel in case of a national emergency; (3) for the coordination of civil and military medical and allied services in times of threatened or actual national emergency, provided that in the exercise of this function there shall be added to the Administration the following members: the Surgeon General, U. S. Army; the Surgeon General, U. S. Navy; the Surgeon General, U. S. Public Health Service; the Air Surgeon; the Medical Director, Veterans Administration; a representative of the National Research Council, and a representative of the American Red Cross.

4. Creation of Council on National Emergency Medical Service: In reference to that part of the report that pertains to the continuous study of this very important assignment, your reference committee concurs in the recommendations of your Committee on National Emergency Medical Service and recommends that this House of Delegates authorize the Board of Trustees of the American Medical Association to create and

appoint a standing committee to be designated as the Council on National Emergency Medical Service.

5. Commendation of Work of Committee: Your reference committee commends the Committee on National Emergency Medical Service for the very exhaustive investigation and study which has resulted in this timely, efficient and epochal conclusive report. It recommends that the House of Delegates extend a vote of thanks to the members of this committee.

Respectfully submitted,

Charles H. Phifer,
Chairman.
Herbert P. Ramsey.
James R. McVay.
Frank L. Cole.
Morton D. Willcutts.
Thomas A. Foster.
George P. Johnston.

Report of Reference Committee on General Medical Practice

Dr. Wingate M. Johnson, Chairman, presented the following report, which was adopted section by section and as a whole, on motions of Dr. Johnson, duly seconded and carried:

Your committee had referred to it the supplementary report of the Council on Medical Education and Hospitals together with a resolution from the Colorado State Medical Society and resolutions from the Medical Society of the County of Kings.

1. Supplementary Report of Council on Medical Education and Hospitals Dealing with Upholding Prestige of General Practitioners: Your committee feels that this report of the Council should do much to clarify the atmosphere so far as the relationship of the general practitioner to hospitals is concerned. Your committee recommends the adoption of this report.

2. Resolution on Change of Policy of American Specialty Boards and Resolutions on Inclusion of General Practitioners on Staffs of Hospitals: Your committee recommends that these resolutions be referred to the Council on Medical Education and Hospitals for consideration and for such recommendations to the specialty boards as may seem warranted.

Respectfully submitted,

Wingate M. Johnson,
Chairman.
Thomas K. Gruber.
Warren L. Allee.
Howard E. Griffin.
H. G. Hamer.
E. Vincent Askey.
Forrest L. Loveland.

The House recessed at 12 noon to reconvene at 1 p. m.

Thursday Afternoon, June 12

The House reconvened at 1 p. m., Thursday, June 12, with the Speaker, Dr. R. W. Fouts, in the chair.

Report of Reference Committee on Credentials

Dr. G. Henry Mundt, Chairman, stated that 173 delegates had been seated.

Roll Call

The Secretary, Dr. George F. Lull, called the roll.

Minutes

On motion of Dr. Val H. Fuchs, Louisiana, seconded by Dr. Clark Bailey, Kentucky, and carried, the House dispensed with the reading of the minutes.

ELECTION OF OFFICERS

Nominations for President-Elect

Dr. F. S. Crockett, Indiana, nominated Dr. R. L. Sensenich, South Bend, Ind., for President-Elect and the nomination was seconded by the delegations from Pennsylvania, Illinois, Alabama, Florida, Rhode Island, New York, Connecticut, Michigan, California, Ohio and Nebraska.

Dr. Walter E. Vest, West Virginia, nominated for President-Elect Dr. James R. Bloss, Huntington, W. Va., and the nomination was seconded by the delegation from Missouri, and Dr. Arthur J. Bedell, Section on Ophthalmology.

On motion of Dr. E. R. Samuel, Pennsylvania, seconded by several and carried, the nominations were closed.

Nomination for Vice President

Dr. James R. Reuling, New York, placed in nomination for Vice President the name of Dr. Thomas A. McGoldrick, Brooklyn. The nomination was seconded by Dr. T. K. Gruber, Michigan.

Dr. Roy B. Henline, Section on Urology, moved that the nominations be closed, and the motion was seconded by several and carried.

Nomination for Secretary

Dr. Arthur J. Bedell, Section on Ophthalmology, nominated Dr. George F. Lull, Chicago, for Secretary. The nomination was seconded by several. On motion, duly made, seconded and carried, nominations for Secretary were closed.

Nomination for Treasurer

The Speaker announced that nominations for Treasurer are submitted by the Board of Trustees.

Dr. Elmer L. Henderson, Trustee, reported that the Board of Trustees placed in nomination for Treasurer the name of Dr. Josiah J. Moore, Chicago, the present Treasurer. On motion of Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by several and carried, the nomination of Dr. Moore was confirmed and the Speaker announced that Dr. Josiah J. Moore was nominated as Treasurer.

Nomination for Speaker of House of Delegates

The Vice Speaker, Dr. F. F. Borzell, assumed the chair and called for nominations for Speaker of the House of Delegates.

Dr. Karl S. J. Hohlen, on behalf of the Nebraska delegation, placed in nomination for Speaker of the House of Delegates the present incumbent, Dr. R. W. Fouts, Omaha, to succeed himself, and the nomination was seconded by several.

Nominations for Speaker of the House of Delegates were then closed on motion regularly made, seconded and carried.

Nomination for Vice Speaker of House of Delegates

The Speaker resumed the chair, and Dr. William Bates, Pennsylvania, placed in nomination for Vice Speaker of the House of Delegates the name of Dr. F. F. Borzell, Philadelphia, and the nomination was seconded by several. On motion of Dr. James Beebe, Delaware, seconded by several and carried, the nominations for Vice Speaker were closed.

Nominations for Trustees

TRUSTEE TO SUCCEED DR. R. L. SENSENICH

Dr. B. J. Hein, Ohio, placed in nomination as Trustee to succeed Dr. R. L. Sensenich, whose term has expired and who is not eligible for reelection, the name of Dr. E. J. McCormick, Toledo, Ohio, and the nomination was seconded by several. On motion duly made, seconded and carried, the nominations for Trustee to succeed Dr. R. L. Sensenich were closed.

TRUSTEE TO SUCCEED DR. DWIGHT H. MURRAY

Dr. John W. Cline, California, placed in nomination the name of Dr. Dwight H. Murray, Napa, Calif., as Trustee to succeed himself, and the nomination was seconded by several.

Dr. F. J. L. Blasingame, Texas, placed in nomination the name of Dr. Britton E. Pickett Sr., Carrizo Springs, Texas, and the nomination was seconded by Dr. Howard E. Griffin, Section on General Practice of Medicine, and Dr. Wingate M. Johnson, North Carolina.

Dr. Harry Eno, Isthmian Canal Zone, placed in nomination the name of Dr. Lloyd Noland, Fairfield, Ala., but Dr. Noland immediately declined the nomination.

On motion regularly made, seconded and carried, the nominations were closed.

The House recessed a few minutes to await the arrival of the President, Dr. Edward L. Bortz.

Nominations by Board of Trustees

NOMINATION FOR MEMBER OF COUNCIL ON MEDICAL EDUCATION AND HOSPITALS TO SUCCEED DR. JOHN H. MUSSER

Dr. Elmer L. Henderson, Trustee, announced that the Board of Trustees placed in nomination as a member of the Council to succeed Dr. John H. Musser, the names of Dr. John H. Musser, New Orleans, and Dr. Wingate M. Johnson, Winston-Salem, N. C.

NOMINATION FOR MEMBER OF COUNCIL ON MEDICAL EDUCATION AND HOSPITALS TO SUCCEED DR. CHARLES GORDON HEYD, RESIGNED

Dr. Elmer L. Henderson, Trustee, announced that Dr. Charles Gordon Heyd, New York, had resigned as a member of this Council and his resignation had been accepted. The Board of Trustees, therefore, placed in nomination to succeed Dr. Heyd the names of Dr. James J. Waring, Denver, and Dr. William S. Middleton, Madison, Wis.

Dr. Wingate M. Johnson withdrew his name from nomination.

NOMINATION FOR MEMBER OF COUNCIL ON MEDICAL SERVICE TO SUCCEED DR. JAMES R. MCVAY

Dr. Elmer L. Henderson for the Board of Trustees placed in nomination to succeed Dr. James R. McVay as a member of the Council on Medical Service the names of Dr. James R. McVay, Kansas City, Mo.; Dr. James Stevenson, Tulsa, Okla., and Dr. Joseph D. McCarthy, Omaha.

NOMINATION FOR MEMBER OF COUNCIL ON MEDICAL SERVICE TO SUCCEED DR. RAYMOND L. ZECH

Dr. Elmer L. Henderson, for the Board of Trustees, stated that Dr. Raymond L. Zech had stated that he could not see his way clear to continue on the Council and for that reason the Board did not nominate him to succeed himself. The Board placed in nomination to succeed Dr. Raymond L. Zech on the Council on Medical Service the names of Dr. Jesse D. Hamer, Phoenix, Ariz., Dr. Raymond F. Peterson, Butte, Mont., and Dr. E. N. Roberts, Pocatello, Idaho.

Dr. James Stevenson, Tulsa, Okla., withdrew his name from nomination, as did Dr. Joseph D. McCarthy, Omaha.

Nominations by President

NOMINATION FOR MEMBER OF JUDICIAL COUNCIL TO SUCCEED DR. LLOYD NOLAND

Dr. Edward L. Bortz, President, nominated Dr. Lloyd Noland to succeed himself as a member of the Judicial Council.

NOMINATIONS FOR MEMBERS OF THE COUNCIL ON SCIENTIFIC ASSEMBLY TO SUCCEED DR. CLYDE L. CUMMER AND DR. EDWARD L. BORTZ

Dr. Edward L. Bortz, President, nominated for membership on the Council to succeed Dr. Clyde L. Cummer the name of Dr. Stanley P. Reimann, Philadelphia, and, to complete the unexpired term of Dr. Edward L. Bortz, the name of Dr. L. B. Jackson, San Antonio, Texas.

Nominations by Board of Trustees

Dr. Elmer L. Henderson, for the Board of Trustees, announced that since Dr. Edward J. McCormick has been proposed for Trustee and is unopposed, this leaves another vacancy on the Council on Medical Service to complete the unexpired term of Dr. McCormick. The Board placed in nomination for this position the names of Dr. Robert Novy, Detroit, Dr. L. Howard Schriver, Cincinnati, and Dr. Elmer Hess, Erie, Pa.

Dr. Schriver withdrew his name from nomination.

Places of *1948, 1949* and *1950* Annual Sessions

After Dr. Robertson Ward, California, had extended an invitation to meet in San Francisco in 1950, Dr. Elmer L. Henderson, for the Board of Trustees, presented the following report:

The Board of Trustees recommends that the 1948 annual session be held in Chicago, and that the 1949 session be held in Atlantic City instead of in St. Louis in 1948 and in New York in 1949 as previously voted. Invitations for the 1950 session have been received from Atlantic City and San Francisco. In view of the fact that many cities are now considering building convention halls and hotels, the Board of Trustees recommends that the selection of the meeting place for 1950 be postponed until the Board of Trustees has more information regarding facilities of various cities for housing a session of the Association.

Dr. T. K. Gruber, Michigan, moved that the House concur in the recommendation of the Board and the motion was seconded by Dr. Thomas S. Cullen, Maryland.

Dr. Hilton S. Read, New Jersey, moved to amend the motion for the House to concur in the recommendations of the Board of Trustees but proceed to vote on the 1950 meeting place as San Francisco. This motion was seconded by Dr. John W. Green, California, and carried after discussion.

The Speaker announced that the motion as amended would be that the annual session in 1948 be held in Chicago, that of 1949 in Atlantic City and that of 1950 in San Francisco. The motion as amended carried.

It was moved by Dr. Rollo K. Packard, Illinois, that the candidates without opposition be elected by acclamation. The motion was seconded by Dr. E. R. Samuel, Pennsylvania, and carried.

The Secretary announced that the following named candidates had no opposition: Dr. Thomas A. McGoldrick, New York, for Vice President for the ensuing year; Dr. George F. Lull, Chicago, for Secretary for the ensuing year; Dr. Josiah J. Moore, Chicago, for Treasurer for the ensuing year; Dr. R. W. Fouts, Omaha, for Speaker of the House of Delegates for the ensuing year; Dr. F. F. Borzell, Philadelphia, for Vice Speaker of the House of Delegates for the ensuing year; for Trustee to succeed Dr. R. L. Sensenich for a term of five years, Dr. E. J. McCormick, Toledo, Ohio; for member of the Judicial Council for a term of five years, Dr. Lloyd Noland, Fairfield, Ala.; for member of the Council on Medical Education and Hospitals for a term of seven years, Dr. John H. Musser, New Orleans; for member of the Council on Scientific Assembly for a term of five years, Dr. Stanley P. Reimann, Philadelphia; for member of the Council on Scientific Assembly to complete the unexpired term of Dr. Edward L. Bortz ending in 1948, Dr. L. B. Jackson, San Antonio, Texas, and for member of the Council on Medical Service for a term of three years, Dr. James R. McVay, Kansas City, Mo.

The Vice Speaker assumed the Chair.

It was moved by Dr. Lowell S. Goin, California, seconded by Dr. Thomas S. Cullen, Maryland, and carried unanimously that the Secretary cast the ballot of the House for each of the nominees without opposition whose names the Secretary had just read and the Secretary cast the ballot of the House electing these candidates and the Vice Speaker declared them elected as indicated.

The ballot sheets were distributed by the tellers for vote on the remaining candidates for office and these ballots were deposited in the ballot box by each delegate on roll call by the Secretary.

On motion of Dr. Forrest J. Pinkerton, Hawaii, duly seconded and carried, the tellers retired to tabulate the ballot.

Nominations for and Election of Affiliate Fellows

Dr. George F. Lull, Secretary, read the following nominations for Affiliate Fellowship made by the various constituent associations and approved by the Council on Scientific Assembly, who were elected to Affiliate Fellowship on motion of Dr. E. S. Hamilton, Illinois, seconded by Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology and carried.

Lisi, Alfred G., Philadelphia.
Sidwell, Albert E. Jr., Chicago.

SECTION ON PATHOLOGY AND PHYSIOLOGY

Field, John, Stanford University, Calif.

Miscellaneous

On motion of Dr. E. S. Hamilton, Illinois, seconded by Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, Dr. Robert T. Devereux, Pennsylvania was granted permission to present a Resolution on Felicitations, no copy of which was presented to the Secretary, which was adopted on motion of Dr. George W. Kosmak, New York, duly seconded and carried.

Dr. E. S. Hamilton, Illinois, moved that the Speaker of the House appoint an interim committee of five or seven men as he sees fit to study methods and means whereby the work of the House can be expedited, the committee to report back at the supplemental session. The motion was seconded by Dr. George W. Kosmak, New York, and carried.

The Vice Speaker, in the Chair, recognized the duly reelected Speaker of the House, who spoke as follows:

I didn't know that was coming, but I do want to take this opportunity to express our very sincere appreciation of the cooperation we have had from the delegates at this session, through the rather long, strenuous sessions, as Dr. Hamilton has just said. It is due wholly to the cooperation that you have given us all the way along that we were able to dispose of many things, and I think most of them in a manner that we will be satisfied with in future days to come.

I also want to express my appreciation and gratefulness for the recognition again tendered me. I will give you my best and hope to see you all again in December. Thank you a lot.

The Vice Speaker spoke as follows: While we are waiting for the final count on the election, may I take this opportunity also to humbly thank the House of Delegates for its renewed acceptance of my services in the past and I hope that we can continue to carry on with your cooperation.

Dr. H. B. Everett, Tennessee, moved that before the House adjourns it would be entirely in order that this House express its appreciation to the Medical Society of New Jersey and the Atlantic City citizens for the hospitality that we have received at this session, which has been fine for the large number of people that we have had here. That should be a part of our record at this meeting, and the local committee should be included. The motion was seconded by several and carried.

Dr. James R. Reuling, New York, moved that in the preparation for this session in Atlantic City, there have been numerous committees who have worked very hard and very long under the chairmanship of Dr. Edward Cunniffe and all members of the committees who have worked so hard to make this, our Centennial Celebration, the grand success it has been, should receive the thanks of this House. The motion was seconded by Dr. Walter E. Vest, West Virginia, and carried.

The Vice Speaker asked if there were any other expressions of appreciation or criticism while we are waiting for the tellers.

Dr. William Bates, Pennsylvania, moved to extend the thanks of this House to all those from 535 North Dearborn Street, who have done everything before and during this session to make our life more pleasant, and the motion was seconded by several.

The Vice Speaker stated that it has been moved and seconded that a vote of thanks be extended to our friends and members of 535 North Dearborn Street, and, if he may be permitted to to state explicitly, Miss Niehoff and Miss Whelan. The motion carried.

Dr. L. J. Kosminsky, Arkansas, moved that the House of Delegates extend a vote of thanks to the retiring President who has done some outstanding work during his year.

The audience arose and applauded, and the Vice Speaker stated that he knew a vote was wanted but that it was obvious.

Dr. H. H. Shoulders, Past President, spoke as follows: I would not dare let this opportunity pass without expressing to you again my very great appreciation of the many courtesies that have been extended to me, the many hospitalities, and the perfectly wonderful cooperation. My memory of the functions of this House goes back a good many years, first as a member, next as a Vice Speaker, next as your Speaker, finally as President-Elect and President. It is a record of which I am very proud, but I am proud of nothing so much as the affection and esteem that you have so graciously displayed.

The Vice Speaker declared a short recess, subject to the receipt of the report of the tellers.

Report of Tellers

The Speaker resumed the chair.

Dr. J. Wallace Hurff, Chairman, reported the results of the election:

The vote for President-Elect was 123 for Dr. R. L. Sensenich and 35 for Dr. James R. Bloss. The Speaker declared Dr. R. L. Sensenich elected to the office of President-Elect of the American Medical Association.

On motion of Dr. Walter E. Vest, West Virginia, duly seconded and carried, the election of Dr. Sensenich was made unanimous.

Dr. Hurff reported that the vote for member of the Board of Trustees to succeed Dr. Dwight H. Murray was 125 for Dr. Murray and 32 for Dr. B. E. Pickett Sr., and the Speaker declared Dr. Dwight H. Murray, Napa, Calif., elected Trustee for a term of five years.

On motion of Dr. B. E. Pickett Sr., Texas, seconded by several and carried, the election of Dr. Dwight H. Murray was made unanimous.

Dr. Hurff reported further that the vote for a member of the Council on Medical Education and Hospitals to fill out the unexpired term of Dr. Charles Gordon Heyd, resigned, expiring in 1951, stood 116 for Dr. William S. Middleton and 26 for Dr. James J. Waring, and the Speaker declared Dr. Middleton elected.

Dr. Hurff reported further that the vote for the election of a member of the Council on Medical Service to fill the unexpired term of Dr. Edward J. McCormick, now a Trustee, to expire in 1949, was 85 for Dr. Elmer Hess and 60 for Dr. Robert Novy. The Speaker declared Dr. Elmer Hess elected.

Dr. Hurff reported the vote for the election of a member of the Council on Medical Service to succeed Dr. Raymond L. Zech, 26 for Dr. R. F. Peterson, 60 for Dr. Jesse D. Hamer and 55 for Dr. E. N. Roberts. The Speaker declared that since no one had received a majority of the votes cast, a new ballot would have to be taken omitting the name of Dr. R. F. Peterson.

The tellers spread the ballot and the Secretary announced that Dr. Hamer had received 44 votes and Dr. Roberts 37. The Speaker declared Dr. Jesse D. Hamer, Phoenix, Ariz., elected a member of the Council on Medical Service for a term of three years.

Address of President-Elect Dr. R. L. Sensenich

Dr. R. L. Sensenich, President-Elect, was presented by the delegation from Indiana and addressed the House as follows:

Mr. Speaker and Members of the House: Anyone who has had so long connection with the affairs of the American Medical Association and has been so proud of its progress could not fail to be fully appreciative of the honor of being selected as its President-Elect. I am greatly honored and I shall do my best to be worthy of that confidence.

I have something a bit more in mind. I don't know that I can in this moment tell it well. Perhaps it is only a bit of emotion that you may discount. We have all had wide contacts and are familiar with the motivations of the individual physician and the objectives and the progress of the Association. This centennial in our history points to our accomplishments, of which we can be very proud. The Association cannot be given all the credit for the improvement in the general health. However, attention must be directed to the fact that twenty-five years added to the average of the lives of 130,000,000 people is a stupendous dividend.

I am very greatly impressed with what physicians and the American Medical Association can do in the years ahead. This centennial, the Scientific Exhibit, the medical program, the actions of this House of Delegates and the support of the membership in expression of unanimous willingness to cooperate in the activities of the American Medical Association are very, very heartening.

However, no one familiar with medical history and progress could fail to recognize the great responsibility that will rest on the medical profession and the American Medical Association. I should like to feel that this Centennial Celebration is in a sense a rededication of the efforts of the medical profession of America to maintain the old traditions, the high motivations and unselfish guidance in directing the progress of medicine and providing public leadership in matters of health.

I hope that as your President-Elect I may be able to emphasize these high motivations of medical men and organizations.

The House adjourned at 4:30 p. m.

Registration at the Centennial Session

The total registration at Atlantic City was 15,667. Below are summaries by sections and daily by states:

Registration by Sections

THE SCIENTIFIC EXHIBIT

The Scientific Exhibit at the Centennial Celebration of the American Medical Association was not only the largest ever presented but also the best in the opinion of numerous visitors. There were many historical exhibits, including rare books and pictures, but the main emphasis was on graduate medical instruction for the physician in the general practice of medicine. Demonstrations were continuous throughout the week in all of the 289 booths, with crowds that taxed the capacity of the aisles. Foreign physicians who were present as guests of the Association expressed amazement at the enormous amount of teaching material presented and at the manner in which physicians of great reputation made themselves accessible to all visitors.

The Special Exhibits subsidized by the Board of Trustees—four in number—were outstanding. The Special Exhibit on Fractures, using five booths, was presented under the auspices of a committee consisting of Dr. Kellogg Speed, Chicago, chairman, Dr. Frank D. Dickson, Kansas City, and Dr. Gordon M. Morrison, Boston. This exhibit has been a feature of the annual sessions almost continuously for twenty years, with Dr. Speed acting as the guiding genius. The Committee on Awards expressed "its deep gratitude, a feeling shared by a whole generation of physicians," to Dr. Speed. A pamphlet describing the exhibit was distributed.

The Special Exhibit on Cardiovascular Diseases occupied seventeen booths. Dr. Paul Dudley White, Boston, was the chairman of a large committee which presented a magnificent display covering all phases of the subject. An interesting feature was a collection of stethoscopes from the earliest models to the present time shown by the Army Institute of Pathology. A pamphlet describing various details of the exhibit was distributed.

The Special Exhibit on Physical Medicine, including physical therapy, occupational therapy and rehabilitation, was shown for the second consecutive year, occupying nine booths. Dr. Frank H. Krusen, Rochester, Minn., chairman, Dr. Winfred Overholser, Washington, D. C., and Dr. Howard A. Rusk, New York, were assisted by a large number of demonstrators. Patients in the various booths added to the interest of the exhibit, requiring a small grandstand to take care of the crowd of visitors. A pamphlet was distributed in connection with the exhibit and motion pictures were shown in an adjoining area.

The Special Exhibit on Fresh Pathologic Material was shown again after a lapse of some years. The committee in charge included Dr. Frank W. Konzelmann, Atlantic City, Dr. Jefferson H. Clark, Philadelphia, and Dr. Edwin S. Gault, Philadelphia, assisted by a large group of demonstrators. Pathologic material was brought daily from Philadelphia for display in addition to material collected in Atlantic City. The constant crowd of visitors at this exhibit gave proof of its teaching value.

Among the many historical exhibits was a group of sixteen booths depicting the activities of the American Medical Association during the past hundred years. Dr. L. M. Tocantins, Philadelphia, contributed material connected with the founding of the Association in 1847 and Dr. Thurman B. Rice, Indianapolis, showed specimens and photographs from the first Scientific Exhibit in 1899.

The Section on Internal Medicine presented a group of twenty-nine exhibits, three of which won awards, including a gold medal. Dr. Thomas C. Garrett, Philadelphia, was the section representative.

The Section on Surgery, General and Abdominal, had twenty-seven exhibits. There were six awards, one of which included a silver medal. Dr. Warren H. Cole, Chicago, was the section representative.

The Section on Obstetrics and Gynecology sponsored a group of ten exhibits, one of which received an award. Dr. Frederick H. Falls, Chicago, was the section representative.

The Section on Ophthalmology presented nine exhibits, one of which received an award. The exhibit committee of the section consisted of Dr. Georgiana D. Theobald, Oak Park, Ill., chairman, Dr. Derrick Vail, Chicago, and Dr. A. B. Reese, New York.

The Section on Laryngology, Otology and Rhinology presented seven exhibits, one of which received an award. The section representative was Dr. Paul H. Holinger, Chicago.

The Section on Pediatrics presented a group of eight exhibits. Dr. Albert V. Stoesser, Minneapolis, was the section representative.

The Section on Experimental Medicine and Therapeutics had fifteen exhibits, one of which won an award. Dr. Robert W. Wilkins, Boston, was the section representative.

The Section on Pathology and Physiology presented fifteen exhibits, two of which received awards. Dr. Frank W. Konzelmann, Atlantic City, N. J., was the section representative.

The Section on Nervous and Mental Diseases presented eight exhibits. The section representative was Dr. A. B. Baker, Minneapolis.

The Section on Dermatology and Syphilology had nine exhibits. There were two awards, one of which was a silver medal. Dr. Francis W. Lynch, St. Paul, was the section representative.

The Section on Preventive and Industrial Medicine and Public Health presented sixteen exhibits. There were three awards, one of which was a bronze medal. Dr. Paul A. Davis, Akron, Ohio, was the section representative.

The Section on Urology presented eleven exhibits, two of which won awards, including a gold medal. Dr. John H. Morrissey, New York, was the section representative.

The Section on Orthopedic Surgery presented eight exhibits with two awards. Dr. David M. Bosworth, New York, was the section representative.

The Section on Gastro-Enterology and Proctology presented ten exhibits. Dr. Donovan C. Browne, New Orleans, served as the section representative.

The Section on Radiology had eleven exhibits. Dr. S. W. Donaldson, Ann Arbor, Mich., served as the section representative.

The Section on Anesthesiology presented six exhibits, one of which received an award. Dr. Urban H. Eversole, Boston, was the section representative.

The Section on General Practice of Medicine presented thirteen exhibits. Dr. J. Craig Bowman, Upper Sandusky, Ohio, served as the section representative.

The Miscellaneous Group included fourteen exhibits, one of which received a bronze medal.

There were two Question and Answer Conferences conducted throughout the week on schedules arranged for each day. Cardiovascular Diseases was presented by a committee of which Dr. E. V. Allen, Rochester, Minn., was chairman. Diabetes was presented under the sponsorship of a group headed by Dr. Howard F. Root, Boston.

The Bureau of Medicine and Surgery, United States Navy, Washington, D. C., presented an exhibit dealing with atomic energy. The Medical Department of the United States Army, Washington, D. C., had a large display showing the activities of the various divisions of the department. The Veterans Administration presented a group of exhibits dealing with its various activities. Each of these services was given a special commendation by the Committee on Awards.

Motion pictures were shown in three rooms adjacent to the exhibits. Fifty-nine pictures were shown each day on a prearranged schedule. Each of the rooms was filled to capacity every day.

Twenty-seven exhibits were presented in connection with papers read before the Scientific Assembly. Forty-five exhibits were also illustrated by motion pictures shown in the motion picture rooms.

REPORT OF THE COMMITTEE ON AWARDS

The Committee on Awards made the following report:

GROUP I

(Awards in Group I are made for exhibits of individual investigations, which are judged on the basis of originality and excellence of presentation.)

The Gold Medal to George E. Burch and Paul Reaser, Tulane Medical School, New Orleans, for the exhibit on Radio Elements and Mechanism of Congestive Heart Failure Radiosodium (Na^{24} and Na^{22}).

The Silver Medal to G. H. Faget, P. T. Erickson and Sister Hilary Ross, U. S. Marine Hospital, Carville, La., for the exhibit on Chemotherapy of Leprosy.

The Bronze Medal to Maurice B. Visscher, A. B. Baker, R. Brown, John Adams, Alan Hemingway, R. Anthony and J. Elam, University of Minnesota, Minneapolis, for the exhibit on the Physiologic Problems of Bulbar Poliomyelitis.

Certificates of Merit, Group I, are awarded to the following (alphabetically arranged):

William H. Feldman and H. Corwin Hinshaw, Mayo Clinic, Rochester, Minn., and Karl Pfuetze, Mineral Springs Sanatorium, Cannon Falls, Minn., for the exhibit on Streptomycin, Experimental and Clinical Observations.

Hugo A. Freund, Gabriel Steiner and Carl E. Duffy, Harper Hospital and Wayne University College of Medicine, Detroit, for the exhibit on Recent Advances in Studies of Rheumatoid Arthritis.

E. S. Gurdjian, J. E. Webster and H. R. Lissner, Wayne University College of Medicine and Grace Hospital, Detroit, for the exhibit on Mechanism of Production of Linear Skull Fracture—Studies with the Stresscoat.

R. J. Huebner and W. L. Jellison, National Institute of Health, U. S. Public Health Service, Bethesda, Md., and Morris Greenberg, City of New York Department of Health, New York, for the exhibit on Rickettsialpox.

In addition, the following exhibits are deemed worthy of Honorable Mention (alphabetically arranged):

That of Leonard F. Bush, C. Zent Garber, William H. Von Lackum and James P. Miller, New York Orthopedic Hospital, New York, on Bone Bank and Homogenous Bone Grafts.

That of Jacob Furth, Cornell University Medical College, New York, on Induction and Characteristics of Ovarian Neoplasms with Hormonal Changes and Hypervolemia.

That of Champ Lyons, H. S. Mayerson and Paul T. DeCamp, Tulane University, New Orleans, on Chronic Shock, the Problem of Reduced Blood Volume in the Chronically Ill Patient.

That of Joe V. Meigs, Ruth M. Graham, Maurice Fremont-Smith, Somers H. Sturgis, Deloris Chapman and Marjorie Soule, Vincent Memorial Hospital, Massachusetts General Hospital, Boston, on Carcinoma of the Cervix: A New Method of Prognosis.

GROUP II

(Awards in Group II are made for exhibits which do not exemplify purely experimental studies but are judged on the basis of excellence of correlating facts and excellence of presentation.)

The Gold Medal to George F. Cahill and Meyer M. Melicow, Squier Urological Clinic, Presbyterian Hospital, New York, for the exhibit on Tumors of the Adrenal Gland.

The Silver Medal to Lester R. Dragstedt, Paul V. Harper, Edward R. Woodward, E. Bruce Tovee and Augustin Rodolfo, University of Chicago Medical School, Chicago, for the exhibit on Gastric Vagotomy in the Treatment of Peptic Ulcer.

The Bronze Medal to Carl F. Jordan and I. H. Borts, Iowa State Department of Health, Des Moines and Iowa City, for the exhibit on Brucellosis.

Certificates of Merit, Group II, are awarded to the following (alphabetically arranged):

Joseph S. Barr, John A. Reidy and James R. Lingley, Massachusetts General Hospital, Boston, and Edward Gall, Bethesda Hospital, Cincinnati, for the exhibit on The Control of Epiphysial Growth by Roentgen Irradiation.

Stuart W. Harrington, Howard K. Gray and O. Theron Clagett, Mayo Clinic, Rochester, Minn., for the exhibit on Surgical Treatment of Certain Intrathoracic Lesions.

Julius Lempert and Dorothy Wolff, Lempert Institute of Otology, New York, and Philip E. Meltzer and LeRoy Schall, Massachusetts Eye and Ear Infirmary, Boston, for the exhibit on the Surgical Treatment of Clinical Otosclerosis.

Albert D. Ruedemann and Otto Glasser, Cleveland Clinic, Cleveland, for the exhibit on the Use of Radium in Ophthalmology.

In addition, the following exhibits are deemed worthy of Honorable Mention (alphabetically arranged):

That of T. J. Dry, J. E. Edwards, R. L. Parker, H. B. Burchell and H. M. Rogers, Mayo Clinic, Rochester, Minn., on Congenital Anomalies of the Heart and Great Vessels; Clinicopathologic Correlation.

That of E. L. MacQuiddy, University of Nebraska College of Medicine, Omaha, on Absorbable Powder Tissue Reactions and Physical Properties.

That of Benjamin T. Terry, Tacoma, Washington, on Razor Section Technic and the Polychroming of Methylene Blue.

That of J. Ross Veal, Georgetown University Medical School, Washington, D. C., on Hyperhidrosis—Surgical Management.

CERTIFICATE OF APPRECIATION

A Certificate of Appreciation is awarded to W. J. Kolff, Kampen, Holland, with special acknowledgment of the services rendered by T. G. Kroop and A. P. Fishman of Mount Sinai Hospital, New York, in the demonstration of the exhibit.

SUBSIDIZED EXHIBITS

The Committee on Awards commends highly the special exhibits on cardiovascular diseases, fractures, fresh pathologic material and physical medicine sponsored by the Board of Trustees of the American Medical Association. The Committee wishes to express its deep gratitude, a feeling shared with a whole generation of physicians, to Dr. Kellogg Speed, Chicago, for his twenty years of continuous untiring efforts to insure exceptional instructive fracture exhibits.

SPECIAL COMMENDATION

Special commendation is given to the historical exhibits presented by Paul E. Bechet, Elizabeth, N. J., on Synopsis of the More Important Achievements of American Dermatology; Ralph M. Waters, O. S. Orth, F. J. Pohle, Donald R. Kindschi and Lucien E. Morris, University of Wisconsin Medical School, Madison, on One Hundred Years of Chloroform, and A. H. Whittaker, Wayne University School of Occupational Health, Detroit, on the Historical Background of Occupational Diseases.

The Committee on Awards especially commends the exceptional exhibits sponsored by the Medical Department of the United States Army, the Bureau of Medicine and Surgery of the United States Navy, and the Veterans Administration, and extends the thanks of the medical profession for their wholehearted cooperation in continuing to present interesting exhibits at the Annual Meetings of the American Medical Association.

COMMENTS

The wholehearted support and active cooperation of the representatives from the seventeen sections of the Scientific Assembly have made the Centennial scientific exhibits worthy of such an event.

Special mention must be made of the excellent motion pictures which again demonstrate the increasing value of this relatively new innovation in visual education. The ones shown were carefully selected from a large number of worth while films submitted by many individuals. The large attendance at each theater attests the interest of the medical profession in this form of exhibit.

The exhibits sponsored by the American Medical Association showing the progress of medicine during one hundred years of its continued growth have proved of great interest.

The Committee on Awards again wishes to express its thanks and that of the thousands attending the Scientific Exhibit to Dr. Thomas G. Hull, Director, for his broad vision, unselfish devotion and tireless efforts in a truly Herculean task. His work has been crowned with signal success.

Respectfully submitted,

Max M. Peet, Ann Arbor, Chairman.
Arthur W. Allen, Boston.
Francis G. Blake, New Haven.
William P. Herbst, Washington, D. C.
Walter M. Simpson, Dayton, Ohio.

MINUTES OF THE SECTIONS

SECTION ON INTERNAL MEDICINE

Wednesday, June 11—Morning

The meeting was called to order at 9 o'clock by the chairman, Dr. Joseph T. Wearn, Cleveland.

Drs. A. Stone Freedburg, Herrman L. Blumgart, Paul M. Zoll and Monroe J. Schlesinger, Boston, presented a paper on "The Clinical Syndrome of Cardiac Pain Intermediate Between Angina Pectoris and Acute Myocardial Infarction, i. e. 'Coronary Failure'." Discussed by Drs. Arthur M. Master, New York; W. D. Stroud, Philadelphia; Robert L. Levy, New York; Joseph T. Wearn, Cleveland, and Herrman L. Blumgart, Boston.

Drs. George E. Burch and Clarence Thorpe Ray, New Orleans, presented a paper on "The Cardiovascular System as the Effector Organ in Psychosomatic Phenomena." Discussed by Drs. George A. Wolf Jr., New York; Mandel E. Cohen, Boston, and George E. Burch, Boston.

Dr. Ernest E. Irons, Chicago, read the Frank Billings Lecture, entitled "Frank Billings, Physician, Teacher and Citizen."

Dr. Richard H. Lyons, Syracuse, N. Y., read a paper on "Experiences with Tetraethylammonium Chloride in Hypertension." Discussed by Drs. K. G. Kohlstaedt, Indianapolis; Eugene Foldes, New York; Frederick M. Allen, New York, and Richard H. Lyons, Syracuse, N. Y.

Dr. Russell S. Boles, Philadelphia, read a paper entitled "An Appraisal of the Modern Medical and Surgical Methods of Treating Peptic Ulcer." Discussed by Drs. Walter L. Palmer, Chicago; Frank H. Lahey, Boston; A. F. R. Andresen, Brooklyn; Samuel Friedman, New York; Asher Winklestein, New York, and Russell S. Boles, Philadelphia.

Thursday, June 12—Morning

The following officers were elected: Chairman, C. J. Watson, Minneapolis; vice chairman, James A. Greene, Houston, Texas; secretary, Walter L. Palmer, Chicago; trustee at large to the Billings Lectureship Fund, N. C. Gilbert, Chicago; delegate, Burrell O. Raulston, Los Angeles; representative to the Scientific Exhibit, Thomas C. Garrett, Philadelphia; executive committee, William D. Stroud, Philadelphia; Joseph T. Wearn, Cleveland; C. J. Watson, Minneapolis.

Dr. A. B. Baker, Minneapolis, read a paper on "The Diagnosis and Treatment of Bulbar Poliomyelitis." Discussed by Drs. John R. Paul, New Haven, Conn.; Hart E. van Riper, New York, and A. B. Baker, Minneapolis.

Drs. Walsh McDermott, Carl Muschenheim and Susan J. Hadley, New York, presented a paper on "Streptomycin in the Treatment of Tuberculosis in Human Beings." Discussed by Drs. J. Burns Amberson, New York; John B. Barnwell, Washington, D. C., and Walsh McDermott, New York.

Dr. Joseph T. Wearn, Cleveland, read the chairman's address, entitled "The Challenge of Functional Disease."

Drs. John S. Hirschboeck, M. C. F. Lindert, Thomas L. Calvy and Jules Chase, Milwaukee, presented a paper on "The Effects of Ethyl Carbamate (Urethane) in the Treatment of Leukemia and Metastatic Malignant Tumors." Discussed by Drs. Claude E. Forkner, New York; Leon O. Jacobson, Chicago; Edwin E. Osgood, Portland, Ore.; William Dameshek, Boston, and John S. Hirschboeck, Milwaukee.

Dr. Leandro M. Tocantins, Philadelphia, read a paper on "The Mechanism and Management of the Hemorrhagic Tendency of Congestive Splenomegaly (Banti's Syndrome)." Discussed by Drs. William Dameshek, Boston, Cecil O. Patterson, Dallas, Texas; C. J. Watson, Minneapolis, and Leandro M. Tocantins, Philadelphia.

Dr. C. H. Slocumb, Rochester, Minn., read a paper on "Concentrated Vitamin D for Rheumatism: Toxic Reactions Simulating Hyperparathyroidism." Discussed by Drs. Richard H. Freyberg, New York; Smith Freeman, Chicago, and C. H. Slocumb, Rochester, Minn.

Friday, June 13—Morning

A joint meeting was held with the Section on Experimental Medicine and Therapeutics.

Dr. Hector Ducci Claro, Santiago, Chile, read the address of the invited foreign guest, on "The Contribution of the Laboratory to the Differential Diagnosis of Jaundice."

Dr. Reginald Fitz, Boston, read the Centennial Address, on the "History of the Specialty of Internal Medicine in the United States."

The following papers were read in a panel discussion on "Recent Advances in Treatment," Dr. Morris Fishbein, Chicago, acting as moderator:

Dr. Thomas M. Rivers, New York, "Virus Diseases."

Dr. Henry L. Bockus, Philadelphia, "Gastrointestinal Diseases."

Dr. Arlie R. Barnes, Rochester, Minn., "Cardiovascular Diseases."

Dr. C. P. Rhoads, New York, "Cancer."

Dr. Russell L. Haden, Cleveland, "Blood Diseases."

Dr. Chester S. Keefer, Boston, "Infectious Diseases."

Dr. James J. Waring, Denver, "Pulmonary Diseases."

Dr. Willard O. Thompson, Chicago, "Endocrinology."

SECTION ON SURGERY, GENERAL AND ABDOMINAL

Wednesday, June 11—Afternoon

The meeting was called to order at 2 o'clock by the chairman, Dr. Alton Ochsner, New Orleans.

Sir Heneage Ogilvie, London, England, read the address of the invited foreign guest, entitled "Gastric Surgery After One Hundred Years."

Dr. Alton Ochsner, New Orleans, read the chairman's address, entitled "Carcinoma of the Lung."

Dr. Richard H. Sweet, Boston, read a paper on "Transthoracic Resection of the Esophagus and Cardiac End of the Stomach for Carcinoma: An Analysis of the Postoperative Complications, Causes of Death and Late Results of Operation." Discussed by Drs. Dallas B. Phemister, Chicago; Morris Friedell, Chicago, and Richard H. Sweet, Boston.

Dr. Owen H. Wangensteen, Minneapolis, read a paper on "The Problem of Gastric Cancer." Discussed by Drs. George T. Pack, New York, and Waltman Walters, Rochester, Minn.

Dr. John M. Waugh, Rochester, Minn., read a paper on "Radical Resection of the Head and Total Pancreatectomy for Benign and Malignant Lesions of the Pancreas." Discussed by Drs. Allen O. Whipple, New York, and Richard B. Cattell, Boston.

Drs. Fred W. Rankin and Coleman C. Johnston, Lexington, Ky., presented a paper on "Surgical Management of Cancer of the Colon and Rectum." Discussed by Drs. Thomas E. Jones, Cleveland; Leland S. McKittrick, Boston, and Frank H. Lahey, Boston.

Thursday, June 11—Afternoon

The following officers were elected: chairman, Dr. B. N. Carter, Cincinnati; vice chairman, Dr. Warren H. Cole, Chicago; secretary, Dr. Michael E. DeBakey, New Orleans; executive committee, Drs. Daniel C. Elkin, Atlanta, Ga.; Alton Ochsner, New Orleans, and B. N. Carter, Cincinnati; delegate, Dr. Grover C. Penberthy, Detroit; alternate, Dr. I. A. Bigger, Richmond, Va.; representative to American Board of Plastic Surgery, Dr. Bradford Cannon, Boston.

Dr. Evarts A. Graham, St. Louis, read the Centennial Address, "A Century of American Surgery."

Dr. Sidney C. Madden, Atlanta, Ga., read a paper on "Protein Nitrogen Retention Following Injury." Discussed by Drs. William Parson, New Orleans, and Sidney C. Madden, Atlanta, Ga.

Dr. Paul R. Cannon, Chicago, read a paper on "The Problem of Amino Acid Utilization in the Surgical Patient." Discussed by Drs. Robert Elman, St. Louis, and Paul R. Cannon, Chicago.

Dr. Champ Lyons, New Orleans, read a paper on "Management of Protein Deficiency in Surgical Patients: Use of Whole Blood Transfusion." Discussed by Drs. Everett I. Evans, Richmond, Va., and Hyman S. Mayerson, New Orleans.

Dr. John D. Stewart, Buffalo, read a paper on "Management of Protein Deficiency in Surgical Patients: Use of Intravenous and Intrajejunal Injections." Discussed by Drs. I. S. Ravdin, Philadelphia, and Robert Elman, St. Louis.

Dr. Richard L. Varco, Minneapolis, read a paper on "Nutritional Problems of Substandard Risk Patients." Discussed by Drs. Donald D. Kozoll, Chicago, and Michael G. Wohl, Philadelphia.

FRIDAY, JUNE 13—AFTERNOON

A joint meeting was held with the Section on Gastro-Enterology and Proctology.

The following papers were read in a symposium on "Peptic Ulcer":

Dr. Maurice Feldman, Baltimore: "Statistical Study of Over 1,000 Cases of Peptic Ulcer."

Drs. Henry A. Rafsky, Michael Weingarten and Charles I. Krieger, New York: "Onset of Peptic Ulcer in the Aged."

Dr. Ervin Levin, Chicago: "Nocturnal Gastric Secretion in Normal Individuals and in Peptic Ulcer."

Drs. H. M. Pollard and William Bachrach, Ann Arbor, Mich.: "Therapeutic Agents: Effect of Enterogastrone in Patient with Gastric and Duodenal Ulcer."

Dr. Leo L. Hardt, Chicago: "Therapeutic Agents: Aluminum Hydroxide Mixture with Mucin in the Treatment of Peptic Ulcer."

Drs. Manfred Kraemer and Leo H. Siegel, Newark, N. J.: "Synthetic Resin: A New Antacid for Treatment in Peptic Ulcer."

Drs. Waltman Walters, Harold A. Neibling, William F. Bradley, John T. Small and James W. Wilson, Rochester, Minn.: "Favorable and Unfavorable Results of Vagus Nerve Resections in the Treatment of Peptic Ulcer: An Anatomic, Physiologic and Clinical Study."

Drs. Samuel F. Marshall, Boston, and Mark L. Welch, Dallas, Texas: "Results of Surgical Treatment for Gastric Ulcer."

Dr. Harold Lincoln Thompson, Los Angeles: "Complications of Peptic Ulcer."

These nine papers were discussed by Drs. Lester R. Dragstedt, Chicago; Sara M. Jordan, Boston; Ralph Colp, New York; Walter L. Palmer, Chicago; Asher Winkelstein, New York; H. B. Stone, Baltimore; M. O. Grossman, Chicago; H. C. Saltzstein, Detroit; Otto De Muth, Vancouver, Canada; Russell S. Boles, Philadelphia; Richard Lewisohn, New York; Mildred Pfeiffer, Philadelphia; Hyman I. Goldstein, Camden, N. J.; David J. Sandweiss, Detroit; A. F. R. Andresen, Brooklyn; Manfred Kraemer, Newark, N. J., and Waltman Walters, Rochester, Minn.

SECTION ON OBSTETRICS AND GYNECOLOGY

WEDNESDAY, JUNE 11—MORNING

The meeting was called to order at 9:10 by the chairman, Dr. Alice F. Maxwell, San Francisco.

Dr. E. A. Schumann, Philadelphia, read the Centennial Address.

Dr. J. Ernest Ayre, Montreal, Canada, read a paper on "Cervical Cytology in the Diagnosis of Early Cancer." Discussed by Drs. Charles E. Galloway, Evanston, Ill.; Arthur Wilson Footer, Oakland, Calif.; Karl H. Martzloff, Portland, Ore.; James Heyman, Stockholm, Sweden; A. E. Rakoff, Philadelphia; Mrs. R. M. Graham, Boston, and J. Ernest Ayre.

Dr. W. D. Beacham, New Orleans, read a paper on "Ectopic Pregnancy." Discussed by Drs. T. J. Williams, University Va.; Charles A. Behney, Philadelphia; Chester M. Echols, Milwaukee; Irving F. Stein, Chicago, and B. Bernard Weinstein, New Orleans.

The following papers were read in a panel discussion on "Gynecologic Bleeding," Dr. A. H. Curtis, Chicago, acting as moderator:

Dr. S. R. M. Reynolds, Baltimore: "Physiologic Basis of Menstruation: A Summary of Current Concepts."

Dr. C. F. Fluhmann, San Francisco: "Menometrorrhagia During Adolescence."

Dr. A. H. Curtis, Chicago: "Functional Bleeding."

Dr. J. P. Pratt, Detroit: "Bleeding Associated with the Menopause."

In the question and answer period Dr. Emil Novak, Baltimore, participated.

THURSDAY, JUNE 11—MORNING

The following officers were elected: chairman, Dr. W. F. Mengert, Dallas, Texas; vice chairman, Dr. R. L. Faulkner, Cleveland; secretary, Dr. Arthur B. Hunt, Rochester, Minn.; executive committee, Drs. P. F. Williams, Philadelphia; Alice F. Maxwell, San Francisco; William F. Mengert, Dallas, Texas; delegate, Dr. Jean Paul Pratt, Detroit; alternate, Dr. Harvey B. Matthews, Brooklyn; delegate to International Congress on Obstetrics and Gynecology in conjunction with Bicentenary of Rotund Hospital, Dublin, Dr. Harvey B. Matthews, Brooklyn.

Dr. Alice F. Maxwell, San Francisco, read the chairman's address, entitled "A Medical Inventory."

Dr. Arthur Grollman, Dallas, Texas, read a paper on "Effect of Pregnancy on Experimental Renal Hypertension." Discussed by Drs. Frank P. Light, Brooklyn; George E. Wakerlin, Chicago, and Arthur Grollman, Dallas, Texas.

Dr. V. S. Counseller, Rochester, Minn., read a paper on "Congenital Absence of the Vagina and Its Surgical Management." Discussed by Drs. F. H. Falls, Chicago; Leo Brady, Baltimore; J. L. Bubis, Cleveland; Arthur H. Curtis, Chicago, and V. S. Counseller, Rochester, Minn.

The following papers were read in a panel discussion on "Modern Indications for Therapeutic Abortion," in which Dr. S. A. Cosgrove, Jersey City, N. J., acted as moderator.

Dr. H. M. Korns, Dubuque, Iowa: "Therapeutic Abortion from the Standpoint of the Internist."

Dr. S. C. Harvey, New Haven, Conn.: "Surgical Indications for Therapeutic Abortion."

Drs. F. G. Ebaugh and Keith D. Heuser, Denver: "Therapeutic Abortion from the Standpoint of the Neuropsychiatrist."

Dr. S. A. Cosgrove, Jersey City, N. J.: "Summary."

FRIDAY, JUNE 13—MORNING

Dr. James Heyman, Stockholm, Sweden, read the address of the invited foreign guest, entitled "Comparability of Material in Evaluating Results of Radiotherapy of Cancer of the Uterine Cervix."

Dr. José Rabago, Mexico City, read a paper on "Cesarean Section at General Hospital of Mexico City.

Dr. William J. Dieckmann, Chicago, read a paper on "Cesarean Hysterectomy." Discussed by Drs. Arthur B. Hunt, Rochester, Minn.; S. A. Cosgrove, Jersey City, N. J.; James F. Norton, Jersey City, N. J.; William F. Mengert, Dallas, Texas, and William J. Dieckmann, Chicago.

The following papers were read in a panel discussion on "Problems of Delivery," Dr. Philip F. Williams, Philadelphia, acting as moderator.

Dr. H. Hudnall Ware Jr., Richmond, Va.: "Unusual and Abnormal Presentations as a Delivery Problem."

Dr. Wiliam F. Windle, Seattle: "Fetal Problems Associated with Delivery."

Dr. C. A. Gordon, Brooklyn: "Hemorrhage as a Delivery Complication."

Dr. Philip F. Williams, Philadelphia: Summary.

SECTION ON OPHTHALMOLOGY

WEDNESDAY, JUNE 11—AFTERNOON

The meeting was called to order at 2:05 by the chairman, Dr. Derrick Vail, Chicago.

Dr. Derrick Vail, Chicago, read the chairman's address.

Surgeon General C. A. Swanson read an address.

Sir Stewart Duke-Elder, London, England, invited foreign guest, read his address, entitled "The Nature of the Aqueous Humor."

Dr. Frederick H. Verhoeff, Boston, read the centennial address, entitled "One Hundred Years of Progress in American Ophthalmology."

Drs. Harold G. Scheie, Philadelphia, Alan S. Crandall, Salt Lake City, and Werner Henle, Philadelphia, presented a paper on "Keratitis Associated with Lymphogranuloma Venereum." Discussed by Drs. John P. Macnie, New York; Garrett L. Sullivan, Boston, and Harold G. Scheie, Philadelphia.

Drs. Peter C. Kronfeld, Chicago, and Isabelle McGarry, Evanston, Ill., presented a paper on "A Five Year Follow-Up of 300 Glaucomatous Eyes." Discussed by Drs. Algernon B. Reese, New York; M. Elliott Randolph, Baltimore, Louis Lehrfeld, Philadelphia; Thomas D. Allen, Chicago, and Peter C. Kronfeld, Chicago.

Thursday, June 12—Afternoon

Dr. Thomas D. Allen, Chicago, read the report of the American Committee on Optics and Visual Physiology. It was voted that the report be received and placed on file.

Dr. Algernon B. Reese, New York, read the report on Awarding the Knapp Medal. It was voted that the report be received and placed on file.

Dr. Phillips Thygeson, San Jose, Calif., read the report of the American Board of Ophthalmology. It was voted that the report be received and placed on file.

The Secretary read the report on the Registry of Ophthalmic Pathology to May 1, 1947. It was voted that the report be accepted and filed.

Dr. Georgiana Dvorak Theobald, Oak Park, Ill., read the report of the Committee on Scientific Exhibit. It was voted that the report be accepted and placed on file.

Dr. Burton Chance, Philadelphia, read the report of the Committee on "Museum of Ophthalmic History." It was voted that the report be accepted and filed.

Dr. Truman L. Boyes, New York, read the report of the American Orthoptic Council. It was voted that the report be accepted and placed on file.

Dr. William L. Benedict, Rochester, Minn., read the report of the Advisory Committee to the Eye Health Committee of the American Student Health Association. It was voted that the report be accepted and filed.

Dr. M. Hayward Post, St. Louis, read the report of the representative of the section to the American College of Surgeons. It was voted that the report be accepted and placed on file.

Dr. Derrick Vail, Chicago, read the report of the Joint Committee of Occupational Ophthalmology. It was voted that the report be accepted and placed on file.

Dr. Parker Heath, Detroit, read the report of the Knapp Testimonial Fund. It was voted that the report be accepted and placed on file.

Dr. Arthur J. Bedell, Albany, N. Y., read his report as delegate to the House of Delegates. It was voted that the report be accepted and filed.

Dr. Conrad Berens, New York, read the report of the executive committee. It was voted that the report be accepted.

The following members were elected to membership on the Committee on Awarding the Knapp Medal. Dr. Fred Davis, Dr. Burton Chance and Dr. S. Judd Beach.

Dr. Louis Lehrfeld, Philadelphia, read the following resolution:

Whereas, A committee of the Philadelphia County Medical Society, consisting of ophthalmologists, obstetricians and bacteriologists, known as a committee to study the efficacy of silver nitrate in the prevention of ophthalmia neonatorum, has definitely gone on record to the effect that silver nitrate has little or no value in the prevention of ophthalmia neonatorum, and

Whereas, Silver nitrate as introduced by Credé in 1884 to prevent ophthalmia neonatorum has outlived its usefulness as compared with the newer antibiotics; and

Whereas, Ophthalmia neonatorum has not been completely eliminated, despite the use of silver nitrate; and

Whereas, Silver nitrate in 1 per cent and 2 per cent solutions may, at times, cause damage to the eyes of the newborn; and

Whereas, The expectant mother who has gonorrhea may be cured by penicillin and other antibiotics; and

Whereas, Forty or more states in the United States now require the use of silver nitrate in the eyes of the newborn despite the fact that the newer antibiotics are specifics against the gonococcus, therefore, be it

Resolved, That the President of the American Medical Association appoint a committee of ophthalmologists, obstetricians and bacteriologists to be known as a "Committee to Revaluate the Use of Silver Nitrate Compared with the New Antibiotics in the Prevention of Ophthalmia Neonatorum" with the express purposes:

1. To eliminate the use of silver nitrate and substitute suitable antibiotics
2. With the view of urging a change in state laws compelling the use of silver nitrate which we now know has little or no value in the prevention of ophthalmia neonatorum; and be it further

Resolved, That such committee cooperate with the present committee of the Philadelphia County Medical Society, which has undertaken a local study of this matter, with the view of having its findings effective on a national and international scale; and be it further

Resolved, That finances to conduct experiments on "Silver Nitrate versus Antibiotics in the Prevention of Ophthalmia Neonatorum" be sought from governmental agencies on research, from governmental agencies dealing with the prevention of venereal disease, and from private agencies interested in the prevention of blindness

It was voted that the resolution be referred to the executive committee for further study and reported back to the section at the next meeting.

A motion was made by Dr. Warren D. Horner, San Francisco, and duly seconded, that the section rescind the various resolutions regarding its attitude toward optometrists in the interest of prevention of blindness and of eye health. After discussion, the motion was put to a vote and defeated.

The following officers were elected: chairman, Dr. Everett L. Goar, Houston, Texas; vice chairman, Dr. Francis Heed Adler, Philadelphia; secretary, Dr. Trygve Gundersen, Boston; delegate, Dr. Arthur J. Bedell, Albany, N. Y.; alternate, Dr. S. Judd Beach, Portland, Maine; executive committee, Dr. Frederick C. Cordes, San Francisco; Dr. Derrick Vail, Chicago, and Dr. Everett L. Goar, Houston, Texas.

Dr. Walter H. Fink, Minneapolis, read a paper on "The Significance of the Ligament of Lockwood in Relation to Surgery of the Inferior Oblique Muscle." Discussed by Drs. Maynard C. Wheeler, New York; Harold F. Falls, Ann Arbor, Mich., and Walter H. Fink, Minneapolis.

Drs. John G. Bellows and Chester J. Farmer, Chicago, presented a paper on "Streptomycin in Ocular Infections." Discussed by Drs. Parker Heath, Detroit; Irving H. Leopold, Philadelphia, and John G. Bellows, Chicago.

Dr. Walter L. Bruetsch, Indianapolis, read a paper on "Unilateral Syphilitic Optic Atrophy." Discussed by Drs. Cecil S. O'Brien, Iowa City; Joseph V. Klauder, Philadelphia, and Walter L. Bruetsch, Indianapolis.

Dr. Leo L. Mayer, St. Louis, read a paper on "Sodium Sulfacetimide 30 per Cent in Ophthalmology." Discussed by Drs. Phillips Thygeson, San Jose, Calif.; Eugene W. Anthony, Fulton, N. Y., and Leo L. Mayer, St. Louis.

Dr. Adolph Posner, New York, presented a tonometer and an attachment to a tangent screen.

Dr. Louis Lehrfeld, Philadelphia, presented an operating head loupe.

Friday, June 13—Afternoon

Drs. Edwin L. Kendig Jr. and DuPont Guerry III, Richmond, Va., presented a paper on "Congenital Impatency of the Nasolacrimal Duct." Discussed by Drs. J. V. Cassady, South Bend, Ind.; John H. Dunnington, New York; Professor Arganaraz, Argentina; Everett L. Goar, Houston, Texas; Edwin L. Kendig Jr., Richmond, Va., and DuPont Guerry III, Richmond, Va.

Dr. George M. Haik, New Orleans, read a paper on "Intraocular Foreign Bodies: Wartime Experiences Applied to a Peacetime Problem." Discussed by Drs. John S. McGavic, Bryn Mawr, Pa , Frank W Newell, Chicago, and George M Haik, New Orleans

Dr Don Marshall, Kalamazoo, Mich , read a paper on "Military Ophthalmology in the European Theater" Discussed by Drs F Phinizy Calhoun Jr , Atlanta, Ga , Trygve Gundersen, Boston, and Don Marshall, Kalamazoo, Mich

Dr S M. Dupertuis, Pittsburgh, read a paper on "Eyelid Reconstruction in the Blinded" Discussed by Drs Norman L Cutler, *Wilmington, Del , Frank McDowell, St Louis, and* S. M. Dupertuis, Pittsburgh.

Drs William C Owens, Baltimore, and William F Hughes Jr , Indianapolis, presented a paper on "Surgical Treatment of Congenital Cataract" Discussed by Drs Frederick C Cordes, San Francisco, and William C Owens, Baltimore

Dr Derrick Vail, the chairman, expressed his thanks to the medical ophthalmic officers who served under him in Europe for their faithful, loyal and excellent service

SECTION ON LARYNGOLOGY, OTOLOGY AND RHINOLOGY

Wednesday, June 11—Morning

The meeting was called to order at 9 05 by the chairman Dr J Mackenzie Brown, Los Angeles

Dr Louis H Clerf, Philadelphia read a paper on 'Progress in Bronchology" Discussed by Drs H B Orton Newark N J , H J Moersch Rochester, Minn , Eelco Huizinga Holland, Andre Soulas, Paris, France, Irving Wilson Voorhees, New York and Louis H Clerf, Philadelphia

Dr Paul H Holinger, Chicago read a paper on "Progress n Esophagology' Discussed by Drs Fletcher D Woodward, Charlottesville Va , E G Gill, Roanoke, Va, and Paul H Holinger, Chicago

Dr Mercer G Lynch, New Orleans read a paper on "Traumatic Injuries of the Larynx, Especially Gunshot Wounds and Their Repair' Discussed by Drs Joseph Buchignani Memphis Tenn , J Wade Youngblood, Dallas, Texas, G E Martin, Edinburgh, Scotland H B Orton, Newark, N J , E G Gill, Roanoke Va , and Mercer G Lynch, New Orleans

Dr Fred Z Havens Rochester, Minn read a paper on Some Technical Procedures in the Treatment of the Cleft Lip nd Palate' Discussed by Drs Harold S Vaughan New York; Robert H Ivy, Philadelphia, George M Dorrance, Philadelphia, Irving Wilson Voorhees, New York, and Fred Z Havens, Rochester, Minn

Dr LeRoy A Schall, Boston, read a paper on 'Malignant Growths of the Nose and Nasal Sinuses" Discussed by Drs Henry B Orton, Newark N J C Stewart Nash, Rochester, N Y , G E Martin, Edinburgh, Scotland, Fred Z Havens, Rochester, Minn and LeRoy A Schall, Boston

Dr A C Furstenberg, Ann Arbor, Mich , read a paper on "Diseases of the Salivary Glands" Discussed by Drs LeRoy A Schall, Boston, James Milton Robb, Detroit, and A C Furstenberg, Ann Arbor, Mich

Dr Murdock Equen, Atlanta, Ga , read a case report entitled "Nail in Duodenum Removed by Magnet"

Dr Gabriel Tucker, Philadelphia, presented a set of instruments for children, and a flexible magnet

Thursday, June 12—Morning

Dr Norton Canfield, New Haven, Conn , made the following recommendation

1. Send the enclosed letter to each member of the Section on Laryngology, Otology and Rhinology of the A M A who served in the armed forces of World War I or World War II

2 Have the secretary of the section summarize the replies and present them to the next meeting of the council for discussion and formulation of further action to be taken at the next meeting of the society.

3 Motion by Dr Carl McCaskey, Indianapolis, seconded by Dr J M. Robb, that Dr Canfield send the following letter and summarize the replies for submission to the council

Dr Canfield was given *authority to send the following letter*

Dear Dr ———

As an otolaryngologist presumably interested in the status of the specialty in programs of federal medicine, such as the Army, Navy and Veterans Administration, will you kindly set forth your views as to the policy which you wish the Section on Laryngology, Otology and Rhinology of the A M A to pursue in regard to organization of the specialty in any existing or future program in which there will be need for special professional services from our members Your reply will be a part of a summary to be presented to the council of the section for discussion and formulation of a policy which will be brought before the next annual meeting of the section

Your officers consider this *request urgent* and *it would* help their activities if we could have your reply by Aug 1 1947 Now is the time for action if we are to be properly represented at the policy making level where professional direction is formulated for the care of patients who require otolaryngologic care in federal medicine programs of the future

The following officers were elected chairman, Dr Fletcher D Woodward, Charlottesville, Va , vice chairman, Dr John R Simpson, Pittsburgh, secretary, Dr J M Robb, Detroit, delegate, Dr Burt R Shurly, Detroit alternate, Dr Gordon Harkness Davenport, Iowa, executive committee Louis H Clerf, Philadelphia, J Mackenzie Brown, Los Angeles, and Fletcher D Woodward Charlottesville, Va , representative to Committee on Scientific Exhibit, James B Costen St Louis, representative to board of governors of the American College of Surgeons, James H Maxwell, Ann Arbor Mich

Dr J Mackenzie Brown Los Angeles, read the chairman s address

Dr G Ewart Martin Edinburgh Scotland invited foreign guest, read his address entitled The Present Position of Bronchoesophagology in Great Britain '

Dr Ralph A Fenton Portland, Ore read the centennial address entitled ' A Brief History of Otolaryngology in the United States, 1847 1947"

Dr Carl H McCaskey, Indianapolis, read a paper on "Neck Surgery in Otolaryngology" Discussed by Drs August L Beck, New Rochelle, N Y , Joseph D Kelly, New York, Benjamin Shuster, Philadelphia, Hayes E Martin, New York, and Carl H McCaskey, Indianapolis

Dr Oscar V Batson Philadelphia read a paper on 'Lymphatics of the Head and Neck" Discussed by Dr Hayes E Martin, New York

Friday, June 13—Morning

Dr Thomas G Tickle, New York read a paper on "Surgery of the Seventh Nerve" Discussed by Drs Frank D Lathrop, Boston, Joseph A Sullivan, Toronto, Canada, and Thomas G Tickle, New York

Dr Julius Lempert, New York read a paper on 'The Lempert Fenestra Nov-Ovalis Operation for the Restoration of Practical and Serviceable Unaided Hearing ' Discussed by Drs Marvin F Jones New York, Philip E Meltzer, Boston, Joseph A Sullivan, Toronto, Canada, Arthur L Juers, Chicago, Maurice Saltzman, Philadelphia, Howard House, Los Angeles, and Julius Lempert, New York

Dr Burt R Shurly, Detroit, gave his report as delegate to the House of Delegates, stating there had been established a new Section on Chest Diseases and that the delegate from that section would increase the number in the House of Delegates to 177 He reported that the House of Delegates passed a resolution to request that a new division of the teaching of nursing be made, in that practical nurses should be offered a two years training so that they would be called certificated nurses

Papers were read by the following authors in a panel discussion on "What Can You Do for the Hard of Hearing?" Dr. Francis L Lederer, Chicago, acted as moderator

Dr Harold Westlake, Northwestern University, Chicago; Miss Eva Thompson and Miss Miriam Pauls, U S Naval Hospital, Philadelphia, Professor Herbert Koepp-Baker, Chicago, Col Edward H Truex, Hartford, Conn , and Dr Charles E Kinney, Cleveland

SECTION ON PEDIATRICS

Thursday, June 11—Afternoon

The meeting was called to order at 2 o'clock by the chairman, Dr. Gilbert J. Levy, Memphis, Tenn.

Drs. Robert A. Hingson and Frank E. Whitacre, Memphis, Tenn., Waldo B. Edwards, New York, and Clifford B. Lull, Philadelphia, presented a paper entitled "An Analysis of Newborn Mortality and Morbidity as Influenced by Continuous Caudal Analgesia with Controls in New York, Philadelphia and Memphis." Discussed by Drs. James G. Hughes, Memphis, Tenn.; Joseph B. Sheffery, Washington, D. C., Russel Wilbur Alles, Detroit; Harold W. Adams, Somersworth, N. H., and Robert A. Hingson, Memphis, Tenn.

Drs. Jerome L. Kohn and Alfred E. Fischer, New York, presented a paper on "Management of Whooping Cough in Infants." Discussed by Drs. Ruth G. Aleman, New Orleans; L. Nellis Silverthorne, Toronto, Canada, and Alfred E. Fischer, New York.

Drs. Abraham M. Litvak and Harry Gabel, Brooklyn, presented a paper on "Cerebral Complications in Pertussis." Discussed by Drs. Philip Rosenblatt, Brooklyn; Benjamin Kramer, Brooklyn, and Abraham M. Litvak, Brooklyn.

Drs. J. Victor Greenebaum and Louis A. Lurie, Cincinnati, presented a paper on "Encephalitis as a Causative Factor in Behavior Disorders in Children." Discussed by Drs. Charles Bradley, East Providence, R. I., and Louis A. Lurie, Cincinnati.

Drs. Alton Goldbloom, Herbert H. Jasper and Helen Friedman Brickman, Montreal, Canada, presented a paper on "Electroencephalographic Studies in Acute Poliomyelitis." Discussed by Drs. M. G. Peterman, Milwaukee; David Bodian, Baltimore; John A. Toomey, Cleveland; Meyer A. Perlstein, Chicago, and Alton Goldbloom, Montreal, Canada.

Drs. Preston A. McLendon and Dorothy S. Jaeger-Lee, Washington, D. C., presented a paper on "The Role of Cow's Milk in Gastrointestinal Allergy of Children." Discussed by Drs. W. Ambrose McGee, Richmond, Va., William F. Matthews, Montclair, N. J.; Newell Jones, Hollywood, Calif.; George Piness, Los Angeles, and Preston A. McLendon, Washington, D. C.

Thursday, June 12—Afternoon

The following officers were elected: chairman, Oscar Reiss, Los Angeles; vice chairman, Stanley Gibson, Chicago; secretary, Margaret Mary Nicholson, Washington, D. C.; representative to Scientific Exhibit, Albert V. Stoesser, Minneapolis; executive committee, John Aikman, Rochester, N. Y.; Gilbert J. Levy, Memphis, Tenn.; Oscar Reiss, Los Angeles.

Dr. Hugh L. Dwyer, Kansas City, Mo., read a report in behalf of the trustees of the Jacobi Memorial Fund. On motion by Dr. Dwyer, duly seconded, it was unanimously voted to appropriate $1,500 of this fund toward the expenses of the International Congress of Pediatrics meeting to be held in New York in July.

Drs. Weston M. Kelsey and George T. Harrell Jr., Winston-Salem, N. C., presented a paper on "Management of Tick Typhus (Rocky Mountain Spotted Fever) in Childhood." Discussed by Drs. David M. Greeley, New York; Charles Armstrong, Washington, D. C., and Weston M. Kelsey, Winston-Salem, N. C.

Dr. Robert Debré, Paris, France, read the address of the invited foreign guest, entitled "Deleterious Results of Overdosage of Vitamin D_2 During Infancy."

Dr. Cameron Haight, Ann Arbor, Mich., read a paper on "Congenital Atresia of the Esophagus with Tracheoesophageal Fistula." Discussed by Drs. Brian B. Blades, Washington, D. C.; Arthur B. McGraw, Detroit, and Cameron Haight, Ann Arbor, Mich.

Dr. Dorothy Donley-Dowd, Washington, D. C., read a paper on "Psychotherapy and the Pediatrician." Discussed by Drs. Earl H. Baxter, Columbus, Ohio; Manfred S. Guttmacher, Baltimore; Winfred Overholser, Washington, D. C., and Dorothy Donley-Dowd, Washington, D. C.

Drs. Ralph V. Platou, John Kometani and Norman Woody, New Orleans, presented a paper on "Pediatric Deaths in a Large General Hospital." Discussed by Drs. Edwin Adams Harper, Lynchburg, Va.; John M. Higgins, Sayre, Pa., and Ralph V. Platou, New Orleans.

Friday, June 13—Afternoon

Drs. Robert H. High, Earl H. Spaulding and Amedeo Bondi Jr., Philadelphia, presented a paper entitled "Clinical Application of a Laboratory Method for the Selection of Antibiotic Therapy." Discussed by Drs. Albert J. Bruecken, Pittsburgh; Horace L. Hodes, Baltimore, and Robert H. High, Philadelphia.

Dr. Hugh Leslie Moore, Dallas, Texas, presented a resolution of thanks to the pediatricians of Atlantic City, N. J., for their untiring efforts in perfecting complete arrangements for the meeting of the Section on Pediatrics.

Drs. Lewis A. Koch, Charles A. Weymuller and Elizabeth James, Brooklyn, presented a paper on "Some Practical Measures for the Reduction of Mortality from Premature Birth." Discussed by Drs. Charles C. Chapple, Philadelphia, and Lewis A. Koch, Brooklyn.

Dr. William Weston Jr., Columbia, S. C., read a paper on "Rheumatic Fever in Childhood." Discussed by Drs. Ira Gore, Washington, D. C.; Stanley Gibson, Chicago; Rachel Ash, Philadelphia; Mark P. Schultz, Bethesda, Md., and William Weston Jr., Columbia, S. C.

Drs. Harriet Davis and Joseph Stokes Jr., Philadelphia; John F. Enders, Boston, and Gertrude Henle and Elizabeth P. Maris, Philadelphia, presented a paper on "Immunologic Studies in Mumps." Discussed by Drs. Karl Habel, Bethesda, Md.; Thomas B. Turner, Baltimore, and Joseph Stokes Jr., Philadelphia.

Drs. Wallace Kernodle, Grant Taylor and Wilburt C. Davison, Durham, N. C., presented a paper on "Lye Poisoning in Children." Discussed by Drs. John Aikman, Rochester, N. Y.; Richard R. O'Toole, Pittsburgh, and Wallace Kernodle, Durham, N. C.

SECTION ON EXPERIMENTAL MEDICINE AND THERAPEUTICS

Wednesday, June 11—Afternoon

The meeting was called to order at 2:05 by the chairman, Dr. Carl A. Dragstedt, Chicago.

Dr. Roger I. Lee, Boston, read the Centennial Address, entitled "The 1947 Flowering of the American Century Plant of Therapeutics."

The following papers were read in a symposium on "The Use of Newer Drugs":

Drs. Robert A. Woodbury, George P. Child, G. Frank Jones Jr. and Richard Torpin, Augusta, Ga.: "Asymatrine Hydrobromide in the Treatment of Gastroenteric Hypermotility." Discussed by Drs. Addison W. Simpson Jr., Washington, Ga., and Benedict E. Abreu, San Francisco.

Dr. Leon O. Jacobson, Chicago: "The Use of Nitrogen Mustards in the Treatment of Disease." Discussed by Drs. Alfred Gellhorn, New York; C. C. Sturgis, Ann Arbor, Mich.; William Dameshek, Boston; Perk Lee Davis, Philadelphia, and Leon O. Jacobson, Chicago.

Dr. Isidore Snapper, New York: "Stilbamidine in the Treatment of Multiple Myeloma." Discussed by Dr. William Dameshek, Boston.

Drs. John Luetscher and Warfield T. Longcope, Baltimore: "BAL Therapy in Arsenic and Mercury Poisoning." Discussed by Drs. Marion B. Sulzberger, New York; Harry Gold, New York, and John Luetscher, Baltimore.

Dr. Francis M. Rackemann, Boston: "Use of Antihistaminic Drugs." Discussed by Drs. Franklin A. Kyser, Evanston, Ill.; Richard A. Kern, Philadelphia; Marion B. Sulzberger, New York, and Francis M. Rackemann, Boston.

Thursday, June 12—Afternoon

The following officers were elected: chairman, Walter Bauer, Boston; vice chairman, Dwight L. Wilbur, San Francisco;

secretary, Carl V Moore, St Louis, executive committee E V Allen, Rochester, Minn, Carl A Dragstedt, Chicago, and Walter Bauer, Boston, delegate, E V Allen, Rochester, Minn, alternate, C M Gruber, Philadelphia, representative to Scientific Exhibit, Robert W Wilkins, Boston

Dr Corneille Heymans, Ghent, Belgium, read the address of the invited foreign guest, on "Blood Pressure Homeostasis and Circulatory Failure"

Dr Carl A Dragstedt, Chicago read the chairman's address, entitled "Idiosyncrasy to Drugs"

Drs Robert L Levy, James A L Mathers, Alex A Mueller and John L Nickerson, New York, presented a paper entitled "Effects of Smoking Cigarets on the Heart in Normal Persons and in Cardiac Patients Discussed by Drs Arlie R Barnes, Rochester Minn, David Adlersberg New York H S Connamacher, Newark N J, Herbert F Robb, Belleville Mich, and Robert L Levy, New York

Drs Irving S Wright and William T Foley, New York, presented a paper on "The Role of Anticoagulants in the Treatment of Heart Disease" Discussed by Drs E V Allen Rochester, Minn Herrman L Blumgart Boston, Leo Loewe, Brooklyn, Benjamin Manchester, Washington, D C, F Sterling Nichol Miami Fla, and Irving S Wright New York

Drs Earle M Chapman Reginald H Smithwick Dora Kinsey and William P Chapman, Boston presented a paper entitled "Preliminary Observation of the Effect of Thoracic Sympathectomy on Heart Rate" Discussed by Drs Keith S Grimson, Durham, N C, Corneille Heymans, Ghent Belgium, and Earle M Chapman Boston

FRIDAY, JUNE 13—MORNING

A joint meeting was held with the Section on Internal Medicine The proceedings are reported in the minutes of that section

SECTION ON PATHOLOGY AND PHYSIOLOGY

WEDNESDAY JUNE 11—MORNING

The meeting was called to order at 9 10 by the chairman, Dr J J Moore Chicago

Dr G E Wakerlin, Chicago, read a paper on "The Present Status of the Therapy of Experimental Renal Hypertension" Discussed by Drs Arthur Grollman Dallas, Texas, Corneille Heymans, Ghent, Belgium, and G E Wakerlin Chicago

Dr R H Draeger, Washington, D C read a paper entitled "Medicine at the Crossroads" Discussed by Drs G E Wakerlin, Chicago, and R H Draeger, Washington, D C

Drs Walter L Bierring and Richard F Birge Des Moines, Iowa, presented a paper on "Tumors of the Carotid Gland"

Dr J J Moore, Chicago read the chairman's address, entitled "The Practice of Pathology"

A motion of appreciation to Dr Moore for services rendered the *section was carried by rising vote*

Dr Goran Liljestrand Stockholm Sweden read the address of the invited foreign guest, entitled "Regulation of the Arterial Pulmonary Pressure"

Dr Howard T Karsner, Cleveland read the Centennial Address, on "American Giants of Pathology"

Drs H J Corper and Maurice L Cohn, Denver, presented a paper on "Various Phases of the Use of Streptomycin in Tuberculosis" Discussed by Dr Emil Bogen, Olive View, Calif

THURSDAY, JUNE 12—MORNING

The following officers were elected chairman, Alvin G Foord, Pasadena, Calif, vice chairman, G E Wakerlin, Chicago, secretary, Edwin F Hirsch, Chicago, executive committee, Virgil H Moon, Philadelphia, J J Moore, Chicago, and Alvin G Foord, Pasadena, Calif, delegate, Swen L Larson, West Elmira, N Y, alternate, H J Corper, Denver, representative to Scientific Exhibit, F W Konzelmann, Absecon, N J

The following papers were presented as a symposium on "Virus Diseases"

Dr E W Schultz, Stanford University, Calif "The Present Status of Viruses and Virus Diseases"

Dr Joseph E Smadel, Washington, D C "The Physician and the Virus Diagnostic Laboratory"

Dr Ralph W G Wyckoff, Washington, D C: "The Electron Microscopy of Viruses"

Dr John H Dingle, Cleveland "Common Virus Infections of the Respiratory Tract"

Drs Thomas Francis Jr and Gordon C Brown, Ann Arbor, Mich "Search for Extrahuman Sources of Poliomyelitis Virus"

Dr John G Kidd, New York "Viruses and Virus-like Agents as Causes of Cancer"

These six papers were discussed by Drs R R Spencer, Washington, D C, James P Leake, Washington, D C, E W Schultz, Stanford University, Calif, and Joseph E Smadel, Washington, D C

FRIDAY, JUNE 13—MORNING

The following papers were read in a symposium on "The Present Status of Cancer Research"

Dr R R Spencer, Washington, D C. "The *Meaning* of Cancer Research"

Dr Henry S N Greene, New Haven, Conn "The Biologic Assessment of Tumor Potentialities" Discussed by Drs Stanley P Reimann Philadelphia, E V Cowdry, St Louis, R R Spencer, Washington, D C, Alvin G Foord, Pasadena, Calif, Robert S Stone, San Francisco, and Henry S N Greene, New Haven, Conn

Dr E V Cowdry, St Louis "Epidermal Carcinogenesis" Discussed by Drs R R Spencer, Washington, D C, M J. Shear, Washington, D C, and E V Cowdry, St Louis

Dr M J Shear, Washington, D C "Some Current Trends in Cancer Chemotherapy" Discussed by Drs Shields Warren, Boston, Stanley P Reimann, Philadelphia, E V Cowdry, St Louis, Robert S Stone, San Francisco, and M J Shear, Washington, D C

Dr Shields Warren, Boston "Radioactive Isotopes in the Diagnosis and Treatment of Malignant Disease" Discussed by Drs Robert S Stone, San Francisco, M J Shear, Washington, D C, and Shields Warren, Boston

SECTION ON NERVOUS AND MENTAL DISEASES

WEDNESDAY, JUNE 11—AFTERNOON

The meeting was called to order at 2 10 by the chairman, Dr Roland P Mackay, Chicago

Dr Wallace B Hamby, Buffalo, read a paper on "Spontaneous Subarachnoid Hemorrhage of Aneurysmal Origin, Factors Influencing Prognosis" Discussed by Drs J C Richardson, Toronto, Canada, I S Wechsler, New York, Rudolph Jaeger, Philadelphia, and Wallace B Hamby, Buffalo

Dr Thierry Alajouanine, Paris, France, read the address of the invited foreign guest, on "The History of Neurology and Its Present Day Applications"

Dr Pearce Bailey, Washington, D C, read a paper on "The Program for the Activation of Neurology Under the Veterans Administration" Discussed by Dr J M Nielsen, Los Angeles

Dr Joseph T Roberts, Washington, D C, read a paper on "Ischemia of Peripheral Nerves, Experimental and Clinical Studies on the Role of the Vasa Nervorum" Discussed by Drs Louis J Karnosh, Cleveland, Joseph L Fetterman Cleveland, Samuel B Hadden, Philadelphia, and Joseph T Roberts, Washington, D C

Dr. Walter G. Haynes, Birmingham, Ala., read a paper on the "Surgical Treatment of Intractable Unilateral Cephalalgia." Discussed by Drs. Paul Bucy, Chicago, Roland P. Mackay, Chicago, and Walter G. Haynes, Birmingham, Ala.

Drs. Michael Scott and Henry T. Wycis, Philadelphia, presented a paper entitled "A Survey of the Value of Neurosurgical Treatment for the Relief of Intractable Pain." Discussed by Drs. A. Earl Walker, Chicago, James L. Poppen, Boston; Ernest A. Spiegel, Philadelphia, James W. Watts, Washington, D. C., and Michael Scott, Philadelphia.

Thursday, June 12—Afternoon

Dr. Walter Freeman, Washington, D. C., submitted a report on the American Board of Psychiatry and Neurology.

Dr. Paul C. Bucy, Chicago, submitted a report on the American Board of Neurological Surgery.

The chairman, Dr. Roland P. Mackay, Chicago, submitted a report on the progress of the International Congress on Mental Health. On motion by Dr. Paul C. Bucy, Chicago, seconded by Dr. Walter Freeman, Washington, D. C., it was decided that two participants, with alternates, be appointed to attend the London meeting of the congress.

The following officers were elected: chairman, A. R. Vonderahe, Cincinnati; vice chairman, William A. Smith, Atlanta, Ga.; secretary, Frederick P. Moersch, Rochester, Minn., representative to Scientific Exhibit, A. B. Baker, Minneapolis; delegate, Hans Heinrich F. Reese, Madison, Wis.; alternate, Robert F. Gayle Jr., Richmond, Va., representative to the American Board of Psychiatry and Neurology, Percival Bailey, Chicago.

Dr. Stanley Cobb, Boston, read the Centennial Address, entitled "One Hundred Years of Progress in Neurology, Neurologic Surgery and Psychiatry."

Dr. R. Glen Spurling, Louisville, Ky., read a paper on "Neurosurgery (and the *Neurosurgeon) in World War II.*" Discussed by Dr. M. Barnes Woodhall, Durham, N. C.

Dr. Francis C. Grant, Philadelphia, read a paper entitled "Surgical Experience with Pituitary Tumors." Discussed by Drs. James L. Poppen, Boston; Edgar A. Kahn, Ann Arbor, Mich.; Max Peet, Ann Arbor, Mich., Oscar Hirsch, Boston, and Francis C. Grant, Philadelphia.

Friday, June 13—Afternoon

Dr. Roland P. Mackay, Chicago, read the chairman's address, entitled "The Neurologist Looks at Discipline."

Dr. Nolan D. C. Lewis, New York, read a paper entitled "Research Leads in Contemporary Neurochemistry." Discussed by Drs. Harold E. Himwich, Falston, Md., and J. M. Nielsen, Los Angeles.

Drs. Karl M. Bowman and Jurgen Ruesch, San Francisco, presented a paper on "Personality and Illness." Discussed by Drs. Samuel B. English, Glen Gardner, N. J., and Karl M. Bowman, San Francisco.

Dr. Benjamin McLane Spock, Rochester, Minn., read a paper on "Common Emotional Disturbances in the First Two Years of Life." Discussed by Drs. Karl M. Bowman, San Francisco; Frederick H. Allen, Philadelphia, and Benjamin McLane Spock, Rochester, Minn.

Drs. George N. Thompson and J. M. Nielsen, Los Angeles, presented a paper on "The Organic Paranoid Syndrome." Discussed by Dr. S. Bernard Wortis, New York.

SECTION ON DERMATOLOGY AND SYPHILOLOGY

Wednesday, June 11—Afternoon

The meeting was called to order at 2:05 by the chairman, Dr. Nelson Paul Anderson, Los Angeles.

The chairman announced the appointment of Dr. George C. Andrews, New York, to the executive committee in the absence of Dr. Clark W. Finnerud, Chicago.

Dr. Francis W. Lynch, St. Paul, read the report on the Scientific Exhibit. Dr. Lynch suggested that the section thank Dr. Paul E. Bechet, Elizabeth, N. J., for the extensive effort put into the preparation of his exhibit. On motion by Dr. Clyde L. Cummer, Cleveland, seconded by Dr. John G. Downing, Boston, it was voted that Dr. Lynch's report be accepted.

Dr. C. Guy Lane, Boston, read the report of the Committee on Industrial Dermatoses, in the absence of Dr. H. F. Foerster, as follows:

> Three meetings of this committee have been held: (1) in Cleveland at the time of the meeting of the American Academy of Dermatology and Syphilology in December 1946, (2) at Murray Bay, Quebec, Canada, June 4, 1947, a joint meeting of the committee with the Advisory Dermatologic Committee of the U. S. Public Health Service, and (3) at Atlantic City, June 12, a joint meeting of this committee with the Advisory Dermatologic Committee of the U. S. Public Health Service.
>
> An informal meeting was also held with representatives of the Council of Industrial Health on June 11.
>
> There was considerable discussion in regard to coordination of the work of the Council of Industrial Health and of the office of dermatology of the U. S. Public Health Service, and considerable progress was made with a view to closer cooperation.
>
> There was also considerable discussion on regional representations of the committee; teaching of occupational dermatoses in medical schools; a formulary for use in the management of occupational skin diseases, and the possible publication at intervals by the Council on Industrial Health of a bulletin of material submitted by the committee and of lists of cutaneous hazards in industry.
>
> Respectfully submitted,
>
> H. F. Foerster, Secretary.

On motion by Dr. Fred D. Weidman, Philadelphia, seconded by Dr. Clyde L. Cummer, Cleveland, it was voted that the report of the Committee on Industrial Dermatoses be accepted.

Dr. Earl Osborne, Buffalo, announced that a meeting of the American Academy of Dermatology and Syphilology was to be held in Chicago in December 1947.

Dr. George M. Lewis read the report of the American Board of Dermatology and Syphilology, which was accepted.

Dr. Paul A. O'Leary, Rochester, Minn., editor of the *Archives of Dermatology and Syphilology*, then gave an oral report on his activities as editor and asked for an expression of opinion as to whether the tenth International Congress should be held in 1950 in the United States and whether members were willing to contribute funds for such a congress.

It was voted, on motion by Dr. Harold N. Cole, Cleveland, seconded by Dr. Clyde L. Cummer, Cleveland, that the secretary be authorized to send a telegram to the oldest member in the United States, Dr. William T. Corlett of Cleveland.

Dr. Nelson Paul Anderson, Los Angeles, read the chairman's address, on "Cysts, Sinuses and Fistulas of Dermatologic Interest."

Dr. Oliver S. Ormsby, Chicago, read the Centennial Address, entitled "One Hundred Years' Progress in Dermatology."

R. M. B. MacKenna, London, England, read the address of the invited foreign guest, entitled "Dermatology: The International Outlook."

Dr. Henry E. Michelson, Minneapolis, read a paper on "Sarcoidosis: A Review and an Appraisal." Discussed by Drs. Fred D. Weidman, Philadelphia; Arthur C. Curtis, Ann Arbor, Mich., and Henry E. Michelson, Minneapolis.

Drs. Earl D. Osborne, James W. Jordan, Frank C. Hoak Jr. and Francis J. Pschierer, Buffalo, presented a paper on "Nitrogen Mustard Therapy in Cutaneous Blastomatous Disease." Discussed by Drs. Charles Spurr, Chicago; Leon Goldman, Cincinnati; Frank J. Eichenlaub, Washington, D. C.; Richard S. Weiss, St. Louis, and Earl D. Osborne, Buffalo.

Drs. David I. Macht and Marcus Ostro, Baltimore, presented a paper on "Pemphigus: Experimental and Clinical Studies on the Etiology, Diagnosis and Therapy."

Dr. Arthur W. Grace, Brooklyn, read a paper on "The Causative Agent of Pemphigus Vulgaris."

These two papers were discussed by Drs. Richard S. Weiss, St. Louis; Walter F. Lever, Boston; John G. Downing, Boston; Maurice Oppenheim, Chicago; Ashton L. Welsh, Cincinnati; David I. Macht, Baltimore, and Arthur W. Grace, Brooklyn.

Thursday, June 12—Afternoon

Dr Francis W Lynch, St Paul, announced the award of the silver medal to Drs G H Faget P T Erickson and Sister Hilary Ross, U S Marine Hospital, Carville, La, for the exhibit on *Chemotherapy of Leprosy*

He also announced that special commendation was given to the historical exhibits of Paul E Bechet, Elizabeth, N J, on "Synopsis of the More Important Achievements of American Dermatology"

The following officers were elected chairman, Henry E Michelson, Minneapolis, vice chairman, Carroll Wright, Philadelphia, secretary, Clinton W Lane, St Louis, representative to American Board of Dermatology and Syphilology, Paul A O'Leary, Rochester, Minn, delegate, C F Lehmann, San Antonio, Texas, alternate, Everett Fox, Dallas, Texas

On motion by Dr Clyde L Cummer, Cleveland duly seconded, it was voted that Dr Bechet be given an honorarium to help defray the expense of his exhibit, to be taken from the money in Dr Lynch's Scientific Exhibit fund, the amount to be left to Dr Lynch's discretion

Drs H S Kupperman, R B Greenblatt and R B Dienst, Augusta, Ga, presented a paper on 'Streptomycin in the Therapy of Granuloma Inguinale" Discussed by Drs Robert R Kierland, Rochester, Minn, Donald M Pillsbury, Philadelphia, Pa, Harold L Hirsh, Washington, D C, Harry M Robinson, Baltimore, and R B Greenblatt Augusta, Ga

Dr Paul A O'Leary, Rochester Minn read the Centennial Address, entitled "A Brief History of Syphilis During the Past Hundred Years"

Drs James K Howles, New Orleans, and Elmer R Gross, Philadelphia, presented a paper on Nonspecific Treatment of ermatoses and Adjunctive Therapy of Syphilis with Oral dium Bismuth Triglycollamate Discussed by Drs Dudley E Smith, Charlottesville Va, Arthur W Neilson St Louis, Harold N Cole, Cleveland Carroll S Wright, Philadelphia, Charles R Rein, New York, and E R Gross, Philadelphia

Dr Eugene A Hand, Saginaw Mich, read a paper on The Importance of Circumcision in the Prevention of Venereal Disease and Certain Forms of Cancer" Discussed by Drs John E Rauschkolb, Cleveland, Francis A Ellis Baltimore, Harry M Robinson, Baltimore, Isidore Snapper, New York, S J Zakon, Chicago, I P McCarthy, Boston and Eugene A Hand, Saginaw, Mich

Drs G H Faget and Paul T Erickson, Carville, La presented a paper on "The Chemotherapy of Leprosy" Discussed by Drs Harold M Johnson, Honolulu, Hawaii, M T Von Studdiford, New Orleans, and Paul T Erickson, Carville, La

Drs Samuel M Peck, Sheppard Siegal, Arthur W Glick and Abner Kurtin, New York, presented a paper on "Clinical Problems in Penicillin Sensitivity" Discussed by Drs Harold N Cole, Cleveland, E Myles Standish, Hartford, Conn, Harry M Robinson, Baltimore, Leon Goldman Cincinnati, E E Mandel, Chicago, Marion B Sulzberger, New York, and Sheppard Siegal, New York

Friday, June 13—Afternoon

Drs H J Templeton, C J Lunsford and H V Allington, Oakland, Calif, presented a paper on "Autosensitization Dermatitis" Discussed by Drs C F Lehmann, San Antonio, Texas, Everett R Seale, Houston, Texas, and R M B MacKenna, London, England

Drs Theodore Cornbleet and Meyer Brown, Chicago, presented a paper on "Dermatologic Manifestations as Presenting Symptoms of Psychiatric Disorders" Discussed by Drs Marion B Sulzberger, New York, Francis W Lynch, St Paul, and Adrian Scolten, Portland, Maine

Drs Frank C Combes and Howard T Behrman, New York, presented a paper on "The Technic and Problems of Roentgen Ray Epilation" Discussed by Drs Anthony C Cipollaro, New York, Francis A Ellis, Baltimore, I M Felsher, Chicago, James Louis Pipkin, San Antonio, Texas, George M Lewis, New York, C Guy Lane, Boston, J Walter Wilson, Los Angeles, and Howard T Behrman, New York

Drs June C Shafer, Carl B Braestrup and Jerome K Fisher, New York, presented a paper on 'The Relation of the Exit Dose and Other Dosage Factors to Roentgen Injuries" Discussed by Drs C Guy Lane, Boston, Oris G Hazel, Oklahoma City, J L Schamberg, Philadelphia, Stephen Epstein, Marshfield, Wis, Anthony C Cipollaro, New York, and June C Shafer, New York

Dr G M Crawford, Boston, read a paper on "Injection Therapy for Angiomas" Discussed by Dr H Ford Anderson, Washington, D C

Drs Roy L Kile and Ashton L Welsh Cincinnati, presented a paper on 'The Use of Liquid Oxygen in Dermatology" Discussed by Drs Allen W Pepple Richmond Va, Richard S Weiss St Louis, H V Allington, Oakland, Calif, and Roy L Kile Cincinnati

The retiring chairman thanked all those who gave and discussed papers, those who spent long hours in preparing scientific exhibits, the Atlantic City hosts the Local Committee on Dermatology and Syphilology the management of the Marlborough-Blenheim Hotel and its personnel

The newly elected officers were then installed On motion by Dr Clyde L Cummer, Cleveland, seconded by Dr C Guy Lane Boston and unanimously approved the section extended its thanks and great appreciation to the retiring officers, particularly Dr Anderson who had served the section for four years

SECTION ON PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH

Wednesday, June 11—Morning

The meeting was called to order at 9 20 by the chairman, Dr Clarence O Sappington, Chicago

Dr Clarence O Sappington Chicago read the chairman's address on The Status of Industrial Medicine'

Dr Clarence D Selby, Detroit read the Centennial Address entitled 'Influence of the Section on the Development of Industrial Medicine'

The following papers were read in a symposium on "How Can Qualified Medical Testimony (Scientific Proof) Be Attained in Workmen's Compensation Controversy Mr J W Holloway Jr Chicago acted as moderator Drs D J Galbraith, Toronto Canada George N Edson Jackson Heights, N Y Carey P McCord Detroit A G Kammer, New York, W G Workman Tracy Minn and Mr Theodore C Waters, Baltimore Discussed by Mr Theodore H Goding, New York, Dr Henry H Kessler, Newark N J, Mr W H Nickels Jr, Richmond, Va, and Dr Frederick W Slobe, Chicago

Thursday, June 12—Morning

The following officers were elected chairman R H Riley, Baltimore, vice chairman Oscar A Sander Milwaukee, secretary, Rutherford T Johnstone Los Angeles, delegate Earl D Osborne, Buffalo, alternate, Leverett D Bristol, New York, executive committee E L Stebbins, New York, Clarence O Sappington, Chicago and R H Riley, Baltimore

Dr Louis I Dublin, New York, read a paper on 'The Longevity and Mortality of American Physicians' Discussed by Drs Haven Emerson, New York, and Louis I Dublin New York

Dr Sven Forssman, Tomtedoda Sweden, read the address of the invited foreign guest, entitled "Comparative Practices in Industrial Medicine in Sweden and in the United States"

The following papers were read in a symposium on 'The Need for Industrial Health Education, How, When and to What Extent"

Dr. Robert A. Kehoe, Cincinnati, acting as moderator: "Medical Education in Relation to Industrial Health."

Dr. W. S. McEllroy, Pittsburgh: "Pittsburgh as the Logical Center to Establish a Graduate Program of Training in Industrial Health."

Dr. J. M. Carlisle, Rahway, N. J.

Dr. Leonard J. Goldwater, New York: "Practical Points in the Teaching of Industrial Medicine."

Dr. Henry F. Vaughan, Ann Arbor, Mich.: "The Need for Industrial Health Education."

Dr. James H. Sterner, Rochester, N. Y.: "The Education of the Industrial Hygiene Physician."

Mr. W. C. L. Hemeon, Pittsburgh: "Contribution to a Symposium on the Need for Industrial Health Education."

These papers were discussed by Drs. Raymond Hussey, Detroit; Russell L. Haden, Cleveland; T. Lyle Hazlett, Pittsburgh; Carl M. Peterson, Chicago; L. W. Fetzer, Dallas, Texas, and W. S. McEllroy, Pittsburgh.

Friday, June 13—Morning

Dr. Emil Seletz, Los Angeles, read a paper on "New Incisions and Revised Technics in Peripheral Nerve Surgery." Discussed by Dr. Michael Scott, Philadelphia.

Dr. Victor Ross, New York, read a paper entitled "Preliminary Report on Schick Test Toxin Not Requiring Control in Adults." Discussed by Dr. James P. Leake, Washington, D. C.

Dr. Joseph A. Bell, Bethesda, Md., read a paper on "Diphtheria Immunization with an Alum Precipitated Mixture of Pertussis Vaccine and Diphtheria Toxoid." Discussed by Drs. Victor Ross, New York; Harold B. Wood, Harrisburg, Pa.; Maxwell Stillerman, Great Neck, N. Y.; James P. Leake, Washington, D. C., and Joseph A. Bell, Bethesda, Md.

Drs. Elmer H. Loughlin and Norman R. Stoll, Brooklyn, presented a paper on "Hookworm Infections in American Servicemen, with Reference to the Establishment of Ancylostoma Duodenale in the Southern United States." Discussed by Drs. Harold B. Wood, Harrisburg, Pa., and Norman R. Stoll, Brooklyn.

Drs. Loren D. Moore, Geoffrey Edsall and Vlado A. Getting, Boston, presented a paper on "The Massachusetts Blood and Blood Derivatives Program." Discussed by Drs. I. Jay Brightman, Albany, N. Y.; Loren D. Moore, Boston; Claude P. Brown, Philadelphia, and J. W. Mountin, Washington, D. C.

Drs. L. T. Fairhall and H. T. Castberg, Bethesda, Md., presented a paper on "Observations on the Industrial Hygiene Aspects of the Cemented Tungsten Carbide Industry." Discussed by Drs. H. T. Castberg, Bethesda, Md.; Clarence O. Sappington, Chicago; L. T. Fairhall, Bethesda, Md., and Claude P. Brown, Philadelphia.

SECTION ON UROLOGY

Wednesday, June 11—Morning

The meeting was called to order at 9:05 by the chairman, Dr. Grayson Carroll, St. Louis.

Dr. William P. Herbst, Washington, D. C., read a paper on "The Problem of the Posteriorly Located Renal Pelvis Associated with Ptosis."

Dr. Roy B. Henline, New York, read a paper on "Ureteropelvic Obstructions: Symptoms and Treatment."

These two papers were discussed by Drs. John M. Pace, Dallas, Texas; Clark M. Johnson, San Francisco; James Sargent, Milwaukee; David M. Davis, Philadelphia; T. D. Moore, Memphis, Tenn.; Abraham Hyman, New York; William P. Herbst, Washington, D. C., and Roy B. Henline, New York.

Dr. William F. Braasch, Rochester, Minn., read the Centennial Address, entitled "One Hundred Years of Progress in Urology."

Dr. Lloyd G. Lewis, Washington, D. C., read a paper on "Radical Orchiectomy in the Treatment of Testis Tumors."

Drs. Hans R. Sauer, Ernest M. Watson and Eugene M. Burke, Buffalo, presented a paper on "Tumors of the Testicle."

These two papers were discussed by Drs. Harold P. McDonald, Atlanta, Ga.; John Ormond, Detroit; Lloyd G. Lewis, Washington, D. C., and Ernest M. Watson, Buffalo.

Dr. Lowrain E. McCrea, Philadelphia, read a paper on "Primary Carcinoma of the Seminal Vesicles: Differentiation from Extrarectal and Rectal Carcinoma."

Dr. W. J. Kolff, Kampen, Holland, read a paper entitled "The Artificial Kidney." Discussed by Drs. Abraham Hyman, New York, and W. J. Kolff, Kampen, Holland.

The chairman announced the death of Dr. Ernest Granville Crabtree, Boston. On motion by Dr. Gershom Thompson, Rochester, Minn., seconded by Dr. Harold P. McDonald, Atlanta, Ga., it was voted that the secretary record in the minutes an expression of sorrow at Dr. Crabtree's death and that an appropriate letter be sent to Mrs. Crabtree. The members then stood for a few moments of silent tribute.

Thursday, June 12—Morning

Dr. Clarence G. Bandler, New York, presented the report from the American Board on Urology, which was accepted.

The following officers were elected: chairman, Reed M. Nesbit, Ann Arbor, Mich.; vice chairman, Earl E. Ewert, Boston; secretary, Edward N. Cook, Rochester, Minn.; representative to the Scientific Exhibit, John H. Morrissey, New York; delegate, Roy B. Henline, New York; alternate, Vincent J. O'Conor, Chicago.

The chairman announced the award of the gold medal to Drs. George F. Cahill and Meyer M. Melicow, New York, for their exhibit on Tumors of the Adrenal Gland.

Dr. Edwin Davis, Omaha, read a paper on "Disappearance of Carcinomatous Ulceration of the Bladder Following Bilateral Ureterosigmoidostomy." Discussed by Drs. William P. Herbst, Washington, D. C., and Armando Trabucco, Buenos Aires, Argentina.

Dr. Benjamin S. Barringer, New York, read a paper entitled "Twenty-Five Years of Radon Implantation for Bladder Cancer."

Dr. Charles C. Higgins, Cleveland, read a paper on "Total Cystectomy for Carcinoma of the Bladder."

These two papers were discussed by Drs. Thomas D. Moore, Memphis, Tenn.; Leo Edelman, New York; Benjamin S. Barringer, New York, and Charles C. Higgins, Cleveland.

Dr. Grayson Carroll, St. Louis, read the chairman's address, entitled "A Study of Pseudomonas Aeruginosa and Related Bacillary Infections of the Urinary Tract."

Dr. Frank S. Patch, Montreal, Canada, read the address of the invited foreign guest, on "Epithelial Metaplasia of the Urinary Tract."

Dr. M. M. Melicow, New York, read a paper on "The Pathology of Adrenal Tumors."

Dr. George F. Cahill, New York, read a paper on "Pheochromocytomas."

These two papers were discussed by Drs. Earl E. Ewert, Boston; Seymour F. Wilhelm, New York; M. M. Melicow, New York, and George F. Cahill, New York.

Dr. A. J. Scholl, Los Angeles, read a paper on "Peripelvic Cysts of the Kidney, with Report on Two Cases." Discussed by Dr. Basil A. Hayes, Oklahoma City, and A. J. Scholl, Los Angeles.

Friday, June 13—Morning

Drs. Hamilton W. McKay, H. Haynes Baird and Kenneth Lynch Jr., Charlotte, N. C., presented a paper on "An Analysis of Two Hundred Cases of Urinary Calculi, with Particular Reference to Methods of Management of Ureteral Stones."

Col. James C. Kimbrough and Major John N. Furst, Washington, D. C., presented a paper on "Management of Recurrent Formation of Renal Calculi."

These two papers were discussed by Drs. A. E. Goldstein, Baltimore; Frank C. Hamm, Brooklyn; Henry Sangree, Philadelphia; George Livermore, Memphis, Tenn.; Hamilton W. McKay, Charlotte, N. C., and J. C. Kimbrough, Washington, D. C.

Mr. Terrence J. Millin, London, England, read a paper on "Retropubic Operation for Stress Incontinence in Women."

Dr. Armando Trabucco, Buenos Aires, Argentina, read a paper on "The Bladder in the Genital Prolapse."

These two papers were discussed by Drs. Virgil S. Counseller, Rochester, Minn.; J. C. Kimbrough, Washington, D. C.; Terrence J. Millin, London, England, and Armando Trabucco, Buenos Aires, Argentina.

Drs. Herman L. Kretschmer and Stuyvesant Butler, Chicago, presented a paper on "Prostatic Surgery and Heart Disease." Discussed by Drs. Harold C. Habein, Rochester, Minn.; Thomas A. Morrissey, New York; A. E. Goldstein, Baltimore, and Herman L. Kretschmer, Chicago.

Dr. W. W. Scott, Baltimore, read a paper entitled "Implications of Hyaluronidase in Fertility."

Drs. M. Leopold Brodny and Samuel A. Robins, Boston, presented a paper on "Urethrocystography in the Male Child."

These two papers were discussed by Drs. Monroe E. Greenberger, New York; A. E. Goldstein, Baltimore; Henry Sangree, Philadelphia; W. W. Scott, Baltimore, and M. Leopold Brodny, Boston.

SECTION ON ORTHOPEDIC SURGERY

Wednesday, June 11—Morning

The meeting was called to order at 9:10 by the chairman, Dr. Francis M. McKeever, Los Angeles.

The following papers were read in a panel discussion on "Fractures of the Upper End of the Femur," Dr. Philip D. Wilson, New York, acting as moderator:

Dr. George W. Van Gorder, Boston: "Treatment of Acute Fractures of the Neck of the Femur." Discussed by Dr. John Royal Moore, Philadelphia.

Drs. Mather Cleveland, D. M. Bosworth and F. R. Thompson, New York: "Management of Intertrochanteric Fractures of the Femur." Discussed by Dr. Robert H. Kennedy, New York.

Dr. Richard H. Freyberg, New York: "Medical Management of the Patient with a Fractured Hip."

Dr. Carl E. Badgley, Ann Arbor, Mich.: "Cause, Development and Treatment of Aseptic Necrosis of the Femoral Head Following Fracture of the Hip." Discussed by Dr. Alexander P. Aitken, Boston.

Dr. Harold B. Boyd, Memphis, Tenn.: "Results of Treatment of Fractures of the Upper End of the Femur."

Dr. J. A. Dickson, Cleveland: "Treatment of Ununited Fractures of the Femur."

These six papers were discussed by Drs. Warren White, New York; José Valls, Buenos Aires, Argentina; George W. Van Gorder, Boston; Mather Cleveland, New York; Richard H. Freyberg, New York; Carl E. Badgley, Ann Arbor, Mich.; Harold B. Boyd, Memphis, Tenn., and J. A. Dickson, Cleveland.

Thursday, June 12—Morning

Drs. Paul R. Lipscomb, Melvin S. Henderson and Ralph E. DeForest, Rochester, Minn., presented a paper on "Internal Derangements of the Knee." Discussed by Drs. D M. Bosworth, New York, and E. F. Cave, Boston.

Dr. Francis M. McKeever, Los Angeles, read the chairman's address, entitled "Fracture of the Olecranon Process of the Ulna."

Drs. Armin Klein, Robert J. Joplin and John A. Reidy, Boston, presented a paper on "The Treatment of Slipped Capital Femoral Epiphyses." Discussed by Drs. H. R. McCarroll, St. Louis; Tom Outland, Elizabethtown, Pa.; Frank R. Ober, Boston; William Boyd, Memphis, Tenn.; Carl Badgley, Ann Arbor, Mich.; Joseph S. Barr, Boston; Hiram Winnett Orr, Lincoln, Neb., and John A. Reidy, Boston.

Dr. Edwin W. Ryerson, Chicago, read the Centennial Address, on "One Hundred Years of Orthopedic Surgery."

Friday, June 13—Morning

The following officers were elected: chairman, J. Warren White, Greenville, S. C.; vice chairman, D. M. Bosworth, New York; secretary, Joseph S. Barr, Boston; delegate, Archer O'Reilly, St. Louis; representative to Scientific Exhibit, Tom Outland, Elizabethtown, Pa.

Dr. Carlo S. Scuderi, Chicago, read a paper on "Massive Bone Grafts for the Restoration of Defects in Long Bone." Discussed by Drs. T. C. Thompson, New York; Jesse T. Nicholson, Philadelphia, and Carlos S. Scuderi, Chicago.

Dr. G. Edmund Haggart, Boston, read a paper on "The Value of Conservative Management in Cervicobrachial Pain." Discussed by Drs. I. W. Nachlas, Baltimore; James McAteer, New York, and G. Edmund Haggart, Boston.

Dr. José Valls, Buenos Aires, Argentina, read the address of the invited foreign guest, entitled "Aspiration Biopsy in the Diagnosis of Lesions of the Vertebral Bodies."

Dr. Leonard F. Bush, Danville, Pa., and C. Zent Garber, New York, presented a paper on "The Bone Bank." Discussed by Drs. John R. Cobb, New York; Frank E. Stinchfield, New York; Dallas B. Phemister, Chicago, and Leonard F. Bush, Danville, Pa.

Dr. Herbert John Seddon, Oxford, England, read a paper on "Nerve Lesions Complicating Certain Closed Bone Injuries."

Dr. Paul C. Colonna, Philadelphia, read a paper on "Experimental Production of Aseptic Necrosis." Discussed by Drs. Dallas B. Phemister, Chicago; George O. Eaton, Baltimore, and Paul C. Colonna, Philadelphia.

SECTION ON GASTRO-ENTEROLOGY AND PROCTOLOGY

Wednesday, June 11—Afternoon

The meeting was called to order at 2:05 by the chairman, Dr. Martin S. Kleckner, Allentown, Pa.

Dr. H. J. Moersch, Rochester, Minn., read a paper on "Results of Treatment of Esophageal Varices by Injection of Sclerosing Solution." Discussed by Dr. Cecil O. Patterson, Dallas, Texas.

Dr. Bruce C. Lockwood, Detroit, read a paper on "Congenital Gallbladder Anomalies."

The following papers were read in a symposium on "Liver Disease":

Diagnostic Aspects:

Professor John McMichael, London, England, invited foreign guest: "A Review of Some Clinical and Biochemical Problems of Liver Disease as Revealed by Systematic Biopsy Studies."

Drs. William F. Lipp, Alfred R. Lenzner and A. H. Aaron, Buffalo: "The Accuracy of Diagnosis of Jaundice."

Drs. Hans Popper and Murray Franklin, Chicago: "Differential Diagnosis of Hepatitis by Histologic and Functional Laboratory Methods."

Therapeutic Aspects:

Dr. Frederick Steigmann, Chicago: "The Efficacy of Lipotrophic Substances in the Treatment of Liver Cirrhosis."

These four papers were discussed by Drs. Cecil J. W Minneapolis; Theodore Gillman, Johannesburg, South Af David Adlersberg, New York, and Professor John McM London, England.

Dr. J. Arnold Bargen, Rochester, Minn., read the C Address, entitled "The History of Progress in Our of the Digestive Tract During the Last Century."

The following papers were read in a symposium "Pancreas":

Drs. Moses Behrend and Albert Behrend, P "Chronic Pancreatitis Causing Complete and

ACC. No. 60

Obstruction of the Common Duct: Report of Illustrative Cases."

Dr. Grayson F. Dashiell, Chicago: "Diagnostic Criteria of Carcinoma of the Pancreas."

Drs. Eric E. Wollaeger, Manfred W. Comfort, Arnold E. Osterberg and O. Theron Clagett, Rochester, Minn.: "Functional Efficiency of the Gastrointestinal Tract Following Resection of the Head of the Pancreas (Whipple Operation): Effect of (1) Anastomosing Remaining Pancreas to the Jejunum; (2) Administration of Pancreatin; (3) Variations of the Fat and Nitrogen Content of the Diet."

These three papers were discussed by Drs. Allen O. Whipple, New York; Robert Elman, St. Louis; J. Edward Berk, Philadelphia; Rudolf Schindler, Los Angeles, and Moses Behrend, Philadelphia.

Thursday, June 12—Afternoon

The following officers were elected: chairman, Dr. Sara M. Jordan, Boston; vice chairman, Dr. William H. Daniel, Los Angeles; secretary, Dr. Grant H. Laing, Chicago; delegate, Dr. Louis A. Buie, Rochester, Minn., alternate, Dr. Walter A. Fansler, Minneapolis; representative to American Board of Proctology, Dr. Robert A. Scarborough, San Francisco (for four consecutive one year terms); representative to Scientific Exhibit, Dr. Donovan C. Browne, New Orleans; executive committee, Dr. J. A. Bargen, Rochester, Minn.; Dr. Martin S. Kleckner, Allentown, Pa., and Dr. Sara M. Jordan, Boston.

The following resolution was adopted:

> *Resolved,* That the Committee on Scientific Exhibit of the American Medical Association be requested to authorize the appointment of a proctologist to assist the gastroenterologist as co-representative to the Scientific Exhibit.

Dr. Martin S. Kleckner, Allentown, Pa., read the chairman's address, entitled "Proctologic Surgery of the Large Bowel."

Dr. Saul Schapiro, Brooklyn, read a paper on "The Proctologic Examination of Infants and Children."

Dr. Tom E. Smith, Dallas, Texas, read a paper on "Anterior Pilonidal Cyst."

Drs. Harry E. Bacon and Robert J. Rowe, Philadelphia, presented a paper on "The Preparation and After-Care of the Patient Undergoing Surgery of the Lower Bowel."

These three papers were discussed by Drs. Frank H. Lahey, Boston; Moses Paulson, Baltimore; Edgar J. Poth, Galveston, Texas; Saul Schapiro, Brooklyn, and Robert J. Rowe, Philadelphia.

The following papers were read in a symposium on "Ulcerative Colitis":

Clinical Aspects:

Dr. William Z. Fradkin, Brooklyn: "The Etiologic Diagnosis of Ulcerative Colitis."

Dr. Joseph B. Kirsner, Chicago: "Certain Clinical Aspects of Ulcerative Colitis."

Treatment:

Dr. Moses Paulson, Baltimore: "Total Parenteral Alimentation and Therapy in Ulcerative Colitis: Its Place in Management."

Dr. Richard B. Cattell, Boston: "The Surgical Treatment of Ulcerative Colitis."

These four papers were discussed by Drs. J. A. Bargen, Rochester, Minn.; E. N. Collins, Cleveland; Joseph Felsen, New York; Sidney A. Portis, Chicago; Albert F. R. Andresen, Brooklyn; Garnet W. Ault, Washington, D. C.; Frank H. Lahey, Boston, and Moses Paulson, Baltimore.

The following papers were read in a symposium on "Gastritis and Gastric Neoplasms":

Drs. Leonidas H. Berry and T. Jonathan Cole, Chicago: "Therapy of Chronic Atrophic Gastritis with Eight Years' Gastroscopic Control."

Drs. Anthony Bassler and A. Gerard Peters, New York: "Distinctions Between Gastric Sarcoma and Carcinoma, with Special Reference to the Infiltrating Type of Sarcomas."

Drs. Samuel N. Maimon, Walter Lincoln Palmer and Joseph B. Kirsner, Chicago: "The Prognosis in Gastric Cancer—A Study of Five Year Survivors."

Dr. H. Leonard Bolen, Fall River, Mass.: "The Blood Pattern in Presymptomatic Malignancy of the Gastrointestinal Tract."

These four papers were discussed by Drs. Hyman L. Goldstein, Camden, N. J.; Henry A. Rafsky, New York; Rudolf Schindler, Los Angeles, and Samuel Friedman, New York.

Friday, June 13—Afternoon

A joint meeting was held with the Section on Surgery, General and Abdominal. The proceedings are reported in the minutes of that section.

SECTION ON RADIOLOGY

Wednesday, June 11—Afternoon

The meeting was called to order at 2:05 by the chairman, Dr. Bernard P. Widmann, Philadelphia.

Dr. Gonzalo Esguerra Gomez, Bogota, Colombia, South America, the invited foreign guest, read a paper on "The Question of Cardiac Hypertrophy in Residents of High Altitudes: Radiologic Study Conducted at 8,636 Feet Above Sea Level."

Dr. George W. Holmes, Boston, read the Centennial Address, entitled "Contributions of Radiology to the Diagnosis and Treatment of Disease."

Dr. Leo G. Rigler, Minneapolis, read a paper on "Routine Roentgen Examination of the Stomach of Symptomless Individuals." Discussed by Dr. Paul Swenson, Philadelphia.

Dr. John D. Camp, Rochester, Minn., read a paper on "Nonneoplastic Intracranial Calcification: Roentgenologic Manifestations." Discussed by Dr. Eugene P. Pendergrass, Philadelphia.

Drs. Vincent W. Archer, George Cooper and Norman Adair, University, Va., presented a paper on "Clinical Manifestations of Disease Masked or Modified by Chemotherapy: Increasing Responsibility of the Roentgenologist." Discussed by Dr. George M. Wyatt, Washington, D. C.

Drs. Ira H. Lockwood, Arthur B. Smith and John W. Walker, Kansas City, Mo., presented a paper on "Fundamental Concepts of Radiographic Diagnosis of Lesions of the Kidney." Discussed by Dr. H. Dabney Kerr, Iowa City.

Drs. C. Robert Hughes, John R. Hannan and Bert E. Mulvey, Cleveland, presented a paper entitled "Cholangiography in Stone, Stricture and Surgical Injury of Biliary Ducts."

Thursday, June 12—Afternoon

The following officers were elected: chairman, W. Walter Wasson, Denver; vice chairman, Harry Weber, Rochester, Minn.; representative to Scientific Exhibit, Samuel Donaldson, Ann Arbor, Mich.

Drs. Robert P. Barden and David A. Cooper, Philadelphia, presented a paper entitled "Roentgen Appearance of the Chest in Some Diseases Affecting the Peripheral Vascular System of the Lung." Discussed by Dr. Francis M. Rackemann, Boston.

Drs. L. Henry Garland, San Francisco, and S. F. Thomas, Palo Alto, Calif., presented a paper on "Roentgen Diagnosis of Myocardial Infarction." Discussed by Drs. Philip J. Hodes, Philadelphia, and W. Edward Chamberlain, Philadelphia.

Drs. Marcy L. Sussman and Harold Neuhof, New York, presented a paper on "Pulmonary and Superior Caval Angiography in Relation to Pulmonary and Mediastinal Lesions."

Drs. Max Ritvo and David Davis, Boston, presented a paper on "Clinical and Roentgen Studies of Radiculitis Simulating Coronary Disease." Discussed by Drs. Albert Oppenheimer, Laconia, N. H., and Robert S. Stone, San Francisco.

Dr. Robert Heilig Library
S. M. S. Medical College

Drs. J. Gershon-Cohen and Philip J. Hodes, Philadelphia, presented a paper on "Roentgenographic Examination of Breast Cancer." Discussed by Dr. W. Walter Wasson, Denver.

FRIDAY, JUNE 13—AFTERNOON

Drs. Harry H. Bowing and Robert E. Fricke, Rochester, Minn., presented a paper on "Late Results of Radium Therapy for Carcinoma of the Uterine Cervix." Discussed by Dr. Leda June Stacy, White Plains, N. Y.

Dr. Juan A. del Regato, Columbia, Mo., read a paper on "The Role of Transvaginal Roentgen Therapy in the Treatment of Carcinoma of the Cervix." Discussed by Dr. James A. Corscaden, New York.

Drs. Manuel M. Garcia and Leon J. Menville, New Orleans, presented a paper entitled "Critical Evaluation of Surgical and Radiation Therapy for Carcinoma of the Cervix." Discussed by Drs. Karl H. Martzloff, Portland, Ore., and Dr. James Heyman, Stockholm, Sweden.

Drs. Orville N. Meland, William E. Costolow and John W. Budd, Los Angeles, presented a paper on "The Role of Radiation Therapy in Cancer of the Breast." Discussed by Drs. U. V. Portmann, Cleveland, and Reuben Lavine, Syracuse, N. Y.

Dr. Frederick W. O'Brien, Boston, read a paper on "The Production of Analgesia by X-Radiation." Discussed by Drs. Hugh F. Hare, Boston, and B. J. Toth, Olean, N. Y.

Drs. James F. Kelly, D. Arnold Dowell and John F. Downing, Omaha, presented a paper on "X-Rays in the Prevention and Treatment of Infections." Discussed by Dr. John S. Bouslog, Denver.

Dr. Sidney Rubenfeld, New York, read a paper on "Roentgenologic Treatment of Lymph Nodes and Spleen in Brill-Symmers Disease." Discussed by Dr. Samuel E. Cohen, Elmira, N. Y.

SECTION ON ANESTHESIOLOGY

WEDNESDAY, JUNE 11—MORNING

The meeting was called to order at 9:05 by the chairman, Dr. Charles F. McCuskey, Los Angeles.

On motion by Dr. Ralph M. Tovell, Hartford, Conn., seconded by Dr. Paul M. Wood, New York, it was voted unanimously that the chairman appoint a committee to investigate operating room deaths and to submit a report at the next annual meeting.

Dr. Clarence L. Hebert, Washington, D. C., read a paper on "Balanced Anesthesia for Thoracoplasty." Discussed by Drs. Robert Richard Jones, Battle Creek, Mich., and Robert B. Orr, St. Albans, N. Y.

Dr. Ralph M. Waters, Madison, Wis., read a paper on "Chloroform." Discussed by Drs. Paul M. Wood, New York, and Irving W. Potter, Buffalo.

Dr. Edward B. Tuohy, Rochester, Minn., read a paper on "Anesthesia for Abdominal Surgery." Discussed by Dr. Harry J. Shields, Toronto, Canada.

Dr. Donald E. Hale, Cleveland, read a paper on "Controlled Hypotension by Arterial Bleeding During Operation and Anesthesia." Discussed by Drs. Perry P. Volpitto, Augusta, Ga.; W. James Gardner, Cleveland; Ralph M. Waters, Madison, Wis., and Robert D. Dripps, Philadelphia.

Drs. J. J. Jacoby, J. M. Coon and H. M. Livingstone, Chicago, presented a paper entitled "Effect of Procaine on Liver Function: An Experimental and Clinical Study." Discussed by Drs. Robert D. Dripps, Philadelphia; John Adriani, New Orleans, and Frederick M. Allen, New York.

THURSDAY, JUNE 12—MORNING

The following officers were elected: chairman, Ralph M. Tovell, Hartford, Conn.; vice chairman, Stuart C. Cullen, Iowa City; representative to Scientific Exhibit, Urban Eversole, Boston.

The following nominees were approved by the section for the American Board of Anesthesiology, the board to make final selection of one of the nominees, who will then serve for six years: Drs. Charles F. McCuskey, Los Angeles; Douglass Batten, San Diego, Calif.; Ernest Warnock, Los Angeles.

Dr. Charles F. McCuskey, Los Angeles, read the chairman's address on "The Status of Anesthesiology as a Specialty."

Dr. Frank W. Hartman, Detroit, read a paper entitled "Pathology of Anesthesia." Discussed by Drs. Wesley Bourne, Montreal, Canada; Virgil H. Moon, Philadelphia, and Ivan B. Taylor, Detroit.

Dr. A. R. Hunter, Manchester, England, read the address of the invited foreign guest, entitled "Anesthesia for Operations Within the Vertebral Canal."

Dr. John S. Lundy, Rochester, Minn., read the Centennial Address, entitled "One Hundred Years of Anesthesia."

FRIDAY, JUNE 13—MORNING

Drs. Eunice Christensen and E. G. Gross, Iowa City, presented a paper entitled "A Comparison of the Analgesic Effects in Human Subjects of 6-Dimethyl Amino-4, 4-Diphenyl-3-Heptonone (An-148), Morphine and Meperidine (Demerol) and the Relative Efficiency of An-148 for Preoperative and Postoperative Use." Discussed by Drs. Leo V. Hand, Boston; Benjamin H. Robbins, Nashville, Tenn., and John S. Lundy, Rochester, Minn.

Drs. Henry S. Ruth, Haverford, Pa., Frederick P. Haugen and D. Dwight Grove, Philadelphia, presented a paper entitled "Anesthesia Study Commission: Findings of Eleven Years' Activity." Discussed by Drs. R. J. Whitacre, East Cleveland, Ohio, and Frank H. Lahey, Boston.

Drs. Edwin R. Ruzicka and Morris J. Nicholson, Boston, presented a paper on "Cardiac Arrest." Discussed by Drs. John B. Flick, Philadelphia; Ralph M. Tovell, Hartford, Conn., and Frank H. Lahey, Boston.

Drs. Julia G. Arrowood and Stanley J. Sarnoff, Boston, presented a paper entitled "Use of Differential Spinal Block in the Investigation of Intractable Pain Following Trauma to the Lower Extremity." Discussed by Drs. Meyer Saklad, Providence, R. I., and Joe Baird, Minneapolis.

Dr. John B. Dillon, Los Angeles, read a paper on "Anesthesia in the Aged." Discussed by Drs. Ansel M. Caine, New Orleans, and Mary Karp, Chicago.

SECTION ON GENERAL PRACTICE OF MEDICINE

WEDNESDAY, JUNE 11—MORNING

The meeting was called to order at 9:15 by the chairman, Dr. Paul A. Davis, Akron, Ohio.

Dr. Paul A. Davis, Akron, Ohio, read the chairman's address, entitled "Practice of Medicine Today and the Future."

Dr. Francisco deP. Miranda, Mexico City, Mexico, the invited foreign guest, read a paper on "Nutrition and Endocrinology, with Special Reference to Nutrition Among the Indians of Mexico."

Dr. Walter C. Alvarez, Rochester, Minn., read the Centennial Address, entitled "What Should the General Practitioner Know About This New Psychosomatic Medicine?" Discussed by Dr. Frank N. Allan, Boston.

Dr. Lewis M. Hurxthal, Boston, read a paper on "Differential Diagnosis of Hypogenitalism at Time of Puberty." Discussed by Dr. Wingate M. Johnson, Winston-Salem, N. C.

Dr. Nils P. Larsen, Honolulu, Hawaii, read a paper on "The Use of Fluorine in Pediatrics." Discussed by Drs. William Wolf, New York, and Sixto Y. Orosa, Manila, Philippine Islands.

THURSDAY, JUNE 12—MORNING

The following officers were elected: chairman, Eric A. Royston, Los Angeles; vice chairman, M. B. Casebolt, Kansas City, Mo.; secretary, W. B. Harm, Detroit; executive committee, Eric A Royston, Los Angeles, Paul A Davis Akron, Ohio, and Wingate M Johnson Winston-Salem N C, delegate, Howard F Griffin Graham, Texas, alternate Tom Robinson Salt Lake City.

Dr. L. E. Poole, Glendale Calif read a paper on "The General Practitioner as an Adjunct to the Industrial Surgeon" Discussed by Drs Clarence D Selby Detroit and W B Harm Detroit

Dr Marion B Sulzberger, New York read a paper on "Common Misconceptions in Regard to Dermatology" Discussed by Drs Donald M Pillsbury, Philadelphia, and F W Lynch, St Paul

Dr. Francis D Murphy, Milwaukee, read a paper on "Arterial Hypertension The Diagnosis and Treatment of Its Complications" Discussed by Drs N C Gilbert Chicago, Frederick M Allen, New York and David Ayman Boston

Dr L Lewis Dill Detroit read a paper entitled "The Stuffy Nose" Discussed by Dr G [illegible] Chicago

Drs Arthur R Metz and Raymond H [illegible] Chicago, and Gerrit Dangremond Lake Bluff Ill presented a paper entitled "The [illegible] Melanoma" Discussed by Dr Grover C Penberthy, Detroit

Dr Gilson Colby Engel, Philadelphia read a paper on "Reducing Mortality in Gastric Carcinoma" Discussed by Drs T Grier Miller, Philadelphia, and Eric A Royston Los Angeles

FRIDAY, JUNE 13—MORNING

Dr T E Robinson Salt Lake City read a paper entitled "Further Observations on Dehydration Treatment in Poliomyelitis with Some New Concepts in the Pathologic Physiology of the Disease" Discussed by Dr George J Boines, Wilmington, Del

Drs Robert L McMillan and Charles R Welfare Winston-Salem, N C, presented a paper on "The Treatment of Chronic Auricular Fibrillation with Quinidine Sulfate" Discussed by Dr George T Harrell Jr, Winston Salem N C

Dr. Edward Weiss, Philadelphia read a paper on "Psychotherapy in Everyday Practice" Discussed by Drs O Spurgeon English, Philadelphia, Dr Sidney A Portis Chicago and Dr Herbert F Robb, Belleville, Mich

Dr R B Robins, Camden, Ark, read a paper entitled "Hints in General Surgery" Discussed by Dr Philip Thorek, Chicago

Drs Stuyvesant Butler and William A Thomas Chicago, presented a paper on "Headache" Discussed by Dr Paul A Davis, Akron, Ohio

SECTION ON MISCELLANEOUS TOPICS

Session on History of Medicine

WEDNESDAY, JUNE 11—AFTERNOON

The meeting was called to order at 2 o clock by the acting chairman, Dr. Howard Dittrick, Cleveland Dr A H Whittaker, Detroit, acted as secretary

The following papers were read on the "History of American Medicine"

Dr M P Rucker, Richmond, Va "In the Old Dominion"

Dr Henry R Viets, Boston "In the Massachusetts Bay Colony"

Dr R H Shryock, Philadelphia "In Philadelphia"

Dr E F Horine, Brooks, Ky "In Kentucky and the Mississippi Valley"

Dr E Ashworth Underwood, London, England, read the address of the invited foreign guest, entitled "Spread of the Public Health Movement in England, 1847-1875"

The following papers were read on the "History of Military Medicine"

Dr R E Dyer, Bethesda, Md : "Public Health Service"

Dr L H Roddis, Washington, D C. "United States Navy."

Dr Harold W Jones, Washington, D C. "United States Army"

Session on Physical Medicine

THURSDAY, JUNE 12—AFTERNOON

The meeting was called to order at 2 10 by the chairman, Dr Frank H Krusen, Rochester, Minn

Dr D Y Solandt, Toronto, Canada, read the address of the invited foreign guest, on "The Relationship of Physical Medicine to Industrial Medicine"

Dr Arthur Abramson, a paraplegic of World War II, a patient in a Veterans Administration hospital, now working in the Veterans Administration Medical Rehabilitation program, presented the following resolution, which on motion by Dr Frank R Ober, Boston, seconded by Dr Sidney Licht, Boston, was unanimously adopted

> *Resolved*, That the Section on Physical Medicine, in session at the Centennial Meeting of the American Medical Association hereby expresses its deep gratitude to Mr Bernard M Baruch for his wisdom, vision, leadership and personal generosity in bringing the benefits of physical medicine and rehabilitation to increasing numbers of America's disabled and that a copy of this resolution be forwarded to Mr Baruch with the heartfelt thanks of this assembly

Dr Earl C Elkins, Rochester, Minn, read a paper on "Rehabilitation of Paraplegics"

Drs Arthur L Watkins and Jacob Ellis Finesinger, Boston, presented a paper on "Psychiatric Aspects of Physical Medicine"

Dr Steven M Horvath, Philadelphia, read a paper on "Fundamentals of Physical Medicine of Interest to the General Practitioner"

The following papers were read in a panel discussion on "Physical Medicine in General Practice," with Dr Frank H Krusen Rochester, Minn, acting as moderator

Dr Walter M Solomon, Cleveland "Physical Treatment of Arthritis"

Dr Walter S McClellan, Saratoga Springs, N Y "Physical Medicine in the Treatment of the Aged"

Dr Frank R Ober, Boston: "Physical Medicine and Backache"

Dr Anthony C Cipollaro, New York "Physical Treatment of Common Dermatologic Conditions"

Dr Miland E Knapp, Minneapolis "Physical Medicine in the Management of Fractures"

Session on Allergy

FRIDAY, JUNE 13—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr Harry L Huber, Chicago

Dr Harry L Alexander, St Louis, read a paper on "Allergy in the Perspective of General Medical Practice" Discussed by Dr Stearns S Bullen, Rochester, N Y

Dr Francis C Lowell, Boston, read a paper on "The Newer Concept of Allergy to Drugs and Bacteria" Discussed by Dr. M G Bohrod, Rochester, N Y

Dr Leo H Criep, Pittsburgh, read a paper on "The Practical Aspects of Allergic Rhinitis" Discussed by Dr Theodore L Squier, Milwaukee

Dr Jerome Glaser, Rochester, N Y, read a paper on "Cutaneous Allergy in Pediatric Practice" Discussed by Dr. Rudolph Baer, New York

Dr Samuel M Feinberg, Chicago, read a paper on "The Newer Drugs in the Treatment of Allergic Diseases" Discussed by Dr Leon Unger, Chicago

The following participated in a panel discussion on "The Treatment of Asthma" Drs J Harvey Black, Dallas, Texas, moderator, Charles H Eyerman, St Louis, Louis Tuft, Philadelphia, and George Piness, Los Angeles The discussion was summarized by Dr Robert A Cooke, New York

Washington Letter

(From a Special Correspondent)

July 2, 1947.

Radioisotopes Described as Holding Great Promise to Mankind

The Atomic Energy Commission's medical board of review announced after its first meeting that "no phase of the atomic energy program offers greater promise of benefit to mankind" than the continued supply of radioisotopes. Radioactive counterparts of normal atoms were said to be used in various fields of medical, biologic, agricultural and industrial research. The board also reported that the measures taken by the Atomic Energy Commission for the protection of workers engaged in development of atomic energy had made a "potentially dangerous occupation one of the safest in America." The board stated that the training of research workers "is probably the most important form of support which the commission can give to outside medical and biological research." The medical board was formed to check on commission research in medical fields and to suggest policies on research carried on by nongovernmental agencies. Dr. Robert F. Loeb, Lambert professor of medicine, Columbia University College of Physicians and Surgeons, New York, is chairman.

House Committee Approves Pay Boost for Service Doctors, Dentists

The House Armed Services Committee has approved legislation boosting the pay of Army, Navy and Public Health Service doctors and dentists. Medical men now in the services and those entering within the next two years will receive an additional $100 a month over their regular pay and allowances under the measure. Those rated as specialists in various fields of medicine would, in addition, be given a 25 per cent increase in their base longevity pay. A subcommittee report stated that "civilian practice is so lucrative to a private practitioner that some action must be taken by Congress or there will be insufficient doctors to adequately provide for Army and Navy personnel." The bill excludes young army and navy reserve doctors whose medical education expenses are paid by the government, unless they are from the regular services.

Council to Conduct Hospital Survey

The Hospital Advisory Council of the District of Columbia has announced that it plans to conduct a survey of Washington's hospital and health facilities and needs as a first step toward federal aid in a construction program under the Hospital Survey and Construction Act of 1946. Still under dispute is the transfer of the Nevius tract, adjacent to Arlington National Cemetery, as the site of a large veterans' hospital.

Advocates Federal Agency for Physically Handicapped

Representative Ray J. Madden, Democrat of Indiana, proposed the establishment of a government department devoted to the interests of the nation's 8 million physically handicapped persons at a meeting of the American Federation of the Physically Handicapped. The federation president, Paul Strachan, lauded Robert C. Goodwin, director of the United States Employment Service, for having placed more than 1,300,000 handicapped persons in jobs.

Advocates Including Question on Vaccination in Census Queries

A dermatologist in Brooklyn has asked the Department of Commerce to include in its census queries "Have you ever been successfully vaccinated?". He explained that it would provide accurate figures on the rate of vaccination and should be followed by a federal law making vaccination against smallpox compulsory.

Coming Medical Meetings

Alaska Territorial Medical Association, Fairbanks, July 28-30. Dr. William J. Blanton, Juneau, Secretary.

American Physiotherapy Association, Pacific Grove, Calif., July 6-12. Miss Mildred Elson, 1790 Broadway, New York 19, Secretary.

Medical Legislation

STATE LEGISLATION

Alabama

Bill Introduced.—S. 121 proposes to require all persons within the ages of 13 and 50 years to be examined and x-rayed or otherwise tested for tuberculosis, the test to be performed either by agents of the state board of health or by doctors or technicians approved by the state board of health.

Bill Passed.—H. 151, which passed the house June 10, to amend the law relating to marriages, proposes that each applicant for a marriage license shall file a certificate signed by a legally licensed physician in Alabama or in the state where the applicant resides certifying that the applicant is not infected with syphilis in a communicable stage. The present law requires such an examination for males only.

Connecticut

Bills Passed.—H. 550, which passed the senate June 3, to amend the medical practice act, proposes to grant the board discretion in accepting licenses from other states in lieu of examination. The proposal would further require that a person who has been refused a certificate by the state board of healing arts may not qualify for approval without examination by the license examining board until he has met the requirements of and been certified by the state board of healing arts. S. 329 which passed the senate June 2, proposes to exempt from taxation Connecticut hospitals operating without possibility of profit.

Bills Enacted.—H. 1375, which was approved June 19, creates a division of professional and vocational licensing to include, among others, the state board of healing arts, the medical examining board, the board of osteopathic registration, the board of chiropractic examiners and the board of naturopathic examiners. S. 133, which was approved June 9, provides higher minimum requirements and more rigid supervision of the professional practice of osteopathy in the state.

Florida

Bills Enacted.—H. 257, which became law without approval June 16, 1947, provides for the licensing, inspecting and regulating of hospitals and the creation of an advisory hospital council. S. 245, which was approved May 15, authorizes the superintendent of the Florida State Hospital, when unable to obtain necessary medical personnel from within the state, to employ competent, experienced medical personnel from outside of the state of Florida and provides that personnel so employed shall be exempt from existing requirements of law as to time of residence in the state and also as to requirements relating to the passing of an examination in the basic sciences.

New Jersey

Bills Enacted.—A. 158, which has become chapter 243 of the Laws of 1947, amends the medical practice act by granting the same recognition to Canadian and Newfoundland medical schools as is granted to medical schools of the United States. S. 208, which has become chapter 323 of the Laws of 1947, authorizes the state department of health to purchase and distribute free, in accordance with rules of said department, antibiotics for use in preventing or treating communicable diseases.

Ohio

Bill Enacted.—H. 294, which was approved May 17, amends the law relating to the practice of chiropody by authorizing the state board of medical examiners to adopt rules and regulations permitting in the practice of chiropody the use of such drugs as are necessary to such practice.

Pennsylvania

Bill Passed.—H. 982, which passed the senate June 14, proposes to define chiropody as "the diagnosis and treatment of the ailments of the human foot. This shall not confer the right to amputate any part of foot, leg or toes or the use of any anesthetic other than local for the treatment of any constitutional disease."

Rhode Island

Bill Enacted.—H. 612, which was approved June 2, is a hospital survey and construction act requiring a survey of hospital facilities in the state and the preparation of a program for the construction of additional needed facilities. The law requires the appointment of an advisory hospital council and authorizes the director of the state department of health to apply to the surgeon general for federal funds to assist in either the survey or the construction of new facilities.

South Carolina

Bill Enacted.—H. 761, which was adopted April 30, appoints a commission to make a full investigation of the practices of the board of naturopathic examiners in the state in the matter of issuance of licenses, the examinations and personal qualifications required of applicants to practice naturopathy in the state and the propriety of granting licenses therefor.

Texas

Bill Passed.—H. 217, which passed the senate June 2, proposes, among other things, that any physician duly licensed under the laws of Texas to practice medicine who, when an autopsy is ordered by a justice of the peace, performs the autopsy in good faith in the belief that the order of the autopsy is a valid order, shall not be held liable for damages in the event it should be determined that the order of autopsy made by the justice of the peace was for any reason invalid.

GOVERNMENT SERVICES

ARMY

DISCHARGE OF MEDICAL OFFICERS

The War Department has announced that, effective July 1, all nonvolunteer doctors, dentists, dietitians and Veterinary and Sanitary Corps officers will be eligible for separation on completion of two years' service. Nurses, physical therapists and Medical Administrative Corps officers except those who have volunteered for extended active duty will be eligible for immediate separation. Critically needed medical officers can still be individually retained when it is essential for the proper care of patients, the announcement stated. Thirty-six specialists are still being retained as essential in army hospitals. Major Gen. Raymond W. Bliss, newly appointed Surgeon General, explained that this new demobilization plan will permit the separation of medical specialists who previously have been subject to three years' service, and it will facilitate the reclassification of young doctors in specialist grade.

Service requirements for members of both the Veterinary and the Sanitary Corps will be reduced from thirty-two months to twenty-four months. Practically all nonvolunteer Medical Administrative Corps officers and physical therapists have already been separated, and the reduction in length of service requirements will affect only a handful of these officers. There is no change for dentists, dietitians and nurses.

ARMY AWARDS AND COMMENDATIONS

Colonel Burr Noland Carter

The Legion of Merit has been awarded to Col. Burr Noland Carter, M. C., A. U. S., of Cincinnati. The citation read in part as follows: "He served as assistant director, Surgical Consultants Division, Office of the Surgeon General, from March 13, 1942, to Aug. 13, 1945. The part played by Colonel Carter in the proper assignment of well qualified surgical personnel, the selection of the finest available surgical equipment and supplies for use throughout the Army, the development of sound fundamental professional policies, his work as administrator of an extensive penicillin research program conducted by the Medical Department when little was known about this new drug and, finally, his role in the development of the whole blood and blood plasma programs of the Army were of greatest importance to the Medical Department and to the American soldier. The low mortality rate among the wounded in this war is directly related to Colonel Carter's knowledge, vision, administrative skill and energetic efforts." Dr. Carter graduated from the University of Virginia Medical School in 1919 and entered the military service March 13, 1942.

Colonel Harry A. Bishop

The Legion of Merit has been awarded to Col. Harry A. Bishop, M. C., U. S. Army, who performed exceptionally meritorious service as commanding officer, Welch Convalescent Hospital, Daytona Beach, Fla., from April 1945 to July 1946. The citation states that his energetic devotion to duty, initiative, judgment, leadership and administrative ability has been superior. He has been responsible for the outstanding accomplishment of this hospital in reconditioning and rehabilitation of overseas sick and wounded which has reflected great credit on the service. Dr. Bishop graduated from the University of Maryland School of Medicine, Baltimore, in 1912, and entered military service June 16, 1918.

Colonel Frank L. Cole

The Legion of Merit has been awarded to Col. Frank L. Cole, M. C., U. S. Army. According to the citation, as commanding officer of Wakeman Hospital Center, Camp Atterbury, Indiana, he effectively developed and perfected the organization and functioning of his command from May 1945 to December 1945. Responsible for the supervision of the newly activated center, which included the general hospital having the largest number of authorized beds of any hospital in the Fifth Service Command, in addition to a convalescent hospital of 6,000 beds and an enlisted technicians' school he successfully coordinated its diversified and rapidly expanding activities. Dr. Cole graduated from the University of Illinois College of Medicine in 1914 and entered the military service in March 1917.

Colonel John M. Tamraz

The Legion of Merit has been awarded to Col. John M. Tamraz, M. C., U. S. Army, for exceptionally meritorious conduct in the performance of outstanding service as surgeon, Headquarters, Services of Supply, China-Burma-India Theater, during the period March 1942 to December 1943. Colonel Tamraz effectively solved the many intricate problems coming within his province in connection with the organization of the medical facilities of the Services of Supply, including a highly valuable liaison with the military medical services of the British. His resourcefulness, efficiency, energy and devotion to duty made him of outstanding value in the organization and initial accomplishment of its mission, thereby reflecting great credit on himself and on the armed forces of the United States. Dr. Tamraz graduated from Columbia University College of Physicians and Surgeons, New York, in 1917 and entered the military service in August 1918.

Colonel William B. Foster

The Legion of Merit has been awarded to Col. William B. Foster, M. C., U. S. Army. According to the citation "he performed exceptionally meritorious service as senior medical member of the Secretary of War's Separation Board from January 1944 to February 1946. He devoted long and arduous hours to the professional analysis of thousands of cases involving final separation of officers from active military service. His recommendations, drawn from careful research and analysis of medical records, were strongly reflected in the final decisions rendered by the board." Dr. Foster graduated from Vanderbilt University Medical School in 1916 and entered military service in 1917.

Colonel William F. DeWitt

The Legion of Merit has been awarded to Col. William F. DeWitt, M. C., U. S. Army. The citation read as follows: "He performed meritorious service as staff surgeon, Headquarters, Southeast Air Corps Training Center, from February 1942 to February 1943. With outstanding administrative ability he overcame the difficulties occasioned by the expansion of his duties incident to mobilization. On his assignment to this office he quickly developed it into an efficient and smoothly running organization." Dr. DeWitt graduated from Baylor University College of Medicine, Dallas, Texas, in June 1924 and entered the military service Nov. 15, 1924.

Lieutenant Colonel Leonard W. Hines

The Legion of Merit was recently awarded to Lieut. Col. Leonard W. Hines, M. C., A. U. S., San Francisco. "While serving with the Army Air Forces Training Command, from April 1941 to February 1946" says the citation, he "contributed prominently to the increase of air crew safety, specifically in connection with high altitude flight operations. His outstanding achievements and exemplary devotion to duty reflect great credit on himself and the Army Air Forces." Dr. Hines graduated from the University of California Medical School in 1933 and entered the service April 24, 1941.

Lieutenant Colonel Matthew Molitch

The Army Commendation Ribbon has been awarded to Lieut. Col. Matthew Molitch, M. C., A. U. S., of Atlantic City, N. J., who, according to the citation, did exceptionally meritorious work in the performance of outstanding service as neuropsychiatric consultant, Armored Replacement Training Center, Fort

Knox, Kentucky, from January 1944 to Jan. 10, 1946. Dr. Molitch graduated from the University of Pennsylvania School of Medicine, in 1929 and entered the service July 24, 1942.

Lieutenant Colonel Edwin S. Kagy

The Bronze Star Medal was recently awarded to Lieut. Col. Edwin S. Kagy of New Orleans by direction of the President for outstanding courage and medical ability in protecting the health and lives of fellow prisoners while serving as surgeon and physician at the Omori, Shinagawa, Niigata and Tokyo 3D prison camps in Japan from September 1943 to August 1945. Dr. Kagy graduated from the School of Medicine of Tulane University of Louisiana in New Orleans in 1934 and entered the military service Aug. 5, 1935.

Captain Granville W. Larimore

The Legion of Merit has been awarded to Capt. Granville W. Larimore, M. C., A. U. S., of New York. The citation read in part as follows: While serving in various capacities in the preventive medicine service, Office of the Surgeon General, from August 1943 to September 1945 he performed notably outstanding service. As Chief of the Education Branch, Venereal Disease Control Division, Captain Larimore was a key figure in promoting a complete armywide venereal disease education program. As chief of the Health Education Unit, his responsibilities were extended to all health education matters in the field of preventive medicine. Dr. Larimore graduated from Rush Medical College, University of Chicago, in 1936 and entered the military service in June 1942.

NAVY

MEETING OF NAVY CONSULTANTS

The Board of Consultants to the Bureau of Medicine and Surgery met June 16 at the Naval Medical Center, Bethesda, Md., in connection with the graduate medical training program of the Navy, to review the progress made during the first year of the program (The Journal, June 28, p. 814), and to formulate future plans. The consultants are mostly former Naval Reserve officers, and as members of American specialty boards they are assisting the Navy in providing training which will meet the standards of the American specialty boards.

Those attending the meeting were Drs. W. M. Craig, chairman, Rochester, Minn.; Howard K. Gray, Rochester, Minn.; Marion B. Sulzberger, New York; Alphonse McMahon, St. Louis; E. N. Broyles, Baltimore; Donald Hale, Cleveland; Paul Titus, Pittsburgh; Joseph S. Barr, Boston; J. Roscoe Miller, Chicago; George M. Lyon, Huntington, W. Va.; Wendell Scott, St. Louis; Paul Greely, Chicago, and M. G. Wastmoreland, Chicago. Following the meeting a buffet supper in honor of the members of the board was held at the quarters of Capt. L. O. Stone (MC), U.S.N., at the Naval Medical Center.

NAVY AWARDS AND COMMENDATIONS

Captain Louis H. Roddis

Capt. Louis H. Roddis (MC), has been awarded the Navy Commendation Ribbon for service rendered in World War II as Senior Medical Officer of the U. S. S. *Relief*. The citation reads in part as follows: While serving as senior medical officer of the U. S. S. *Relief* from March 4 to Sept. 9, 1944 his professional skill and devotion to duty contributed to the smooth and efficient functioning of the Medical Department. During fleet concentrations he rendered invaluable consultation service and dealt with many medical problems, both in disease prevention and in evacuation of the sick and wounded. Under his direction, during the capture of Saipan and Tinian, large numbers of serious casualties were embarked and transported, many directly from the beachheads. His performance of duty was outstanding and his conduct was at all times in keeping with the highest traditions of the U. S. Naval Service. Dr. Roddis graduated from the University of Minnesota Medical School in 1913 and entered the naval service in 1914. He is now chief of the publications division of the Bureau of Medicine and Surgery and editor of the *United States Naval Medical Bulletin*.

VETERANS ADMINISTRATION

THE VETERAN POPULATION

According to the latest tabulation by the Veterans Administration there was a total of 18,188,000 living veterans as of May 1, of whom 14,267,000 served in World War II. More than 100,000 veterans live in Alaska, the Canal Zone, Hawaii and Puerto Rico and some 50,000 in foreign countries exclusive of the Philippines. The total number estimated does not include United States citizens who served only in Allied military forces, some of whom are eligible for various Veterans Administration benefits.

CONTRACT FOR LOUISIANA HOSPITAL

The War Department has announced that the Army Corps of Engineers has let the architect-engineer contract for the Veterans Administration hospital at Mound Bayou, La., which will be a 200 bed general medical and surgical hospital. The Mound Bayou is another unit in the construction program involving seventy-four hospitals and the expenditure of $770,000,000 undertaken by the Corps of Engineers for the Veterans Administration.

HOSPITALS AT PITTSBURGH

The Army Corps of Engineers has awarded the architect-engineer contract for the veterans' neuropsychiatric hospital at Pittsburgh and about a week ago made a similar contract for the veterans' general medical and surgical hospital at Pittsburgh. These hospitals will have a capacity of 1,300 and 1,200 beds respectively.

PERSONALS

Dr. Merlin H. Draper, Tampa, has been appointed consultant in tuberculosis to the medical staff of Bay Pines (Florida) Veterans' Hospital. He is at present superintendent and medical director of the Florida State Tuberculosis Sanatorium and previously had been medical director at the Irene Bryon Sanatorium, Fort Wayne, Ind., for nineteen years.

Dr. Cleve C. Odum has become manager of the Veterans Administration hospital at Augusta, Ga., succeeding Dr. Henry O. Witten, who was transferred to a veterans' hospital in California, where he planned to retire.

MISCELLANEOUS

SALE OF SURPLUS GOVERNMENT PROPERTY

The War Assets Administration is conducting sales of surplus government property announced by the following regional offices. Physicians who are veterans have certain priorities in the purchase of surplus government property.

Regional Office, 728 Fifteenth Street, Denver 2. Sale of drugs, laboratory equipment and supplies, hospital and surgical supplies. Sale closes July 8.

Regional Office, 8900 South Broadway, St. Louis. Sale of surgical knives, catheters, bone chisels, forceps, proctoscopes, operating scissors and utensils and dressing sterilizers. Sale closes July 14.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

ARIZONA

Arizona Society of Psychiatry and Neurology.—This society was founded at a meeting on May 7 during the annual meeting of the Arizona State Medical Association at Tucson. The meeting was attended by most of the physicians practicing psychiatry and neurology in the state. Regular meetings are planned for the future. Dr. Otto L. Bendheim, Phoenix, was elected president and Dr. Lindsay E. Beaton, 1650 North Cambell Avenue, Tucson, secretary.

COLORADO

Dr. Sabin Receives Medal.—Dr. Florence R. Sabin, Denver, recently received the first Jane Addams Medal given by Rockford College, Rockford, Ill., for distinguished service by an American woman, for her achievements as a leading spirit in public health programs in Colorado. Dr. Sabin retired a few years ago from the Rockefeller Institute of Medical Research, New York, only to find herself head of the state subcommittee on health, on which she has been very active.

CONNECTICUT

Rural Health Conference.—New England's first all day rural health conference will be sponsored by the Connecticut State Medical Society and the University of Connecticut, New Haven, July 16, with Dr. Norman H. Gardner, East Hampton, chairman. About 300 representatives of civic, social, farm and health agencies will be invited to the conference. The program will include talks by leaders of state and private health agencies and panel discussions on the control of communicable diseases, housing, sanitation, school health, mental health, chronic diseases and dental health. Dr. James R. Miller, Hartford, president of the state medical society, will preside at the morning program.

Dr. Long Succeeds Dr. Blake as Dean at Yale.—Dr. C. N. Hugh Long, Sterling professor of physiologic chemistry, Yale University School of Medicine, New Haven, since 1938, and chairman of the department since 1936, was appointed dean of the medical school beginning July 1 to succeed Dr. Francis G. Blake. Dr. Long took his medical degree at McGill University Faculty of Medicine, Montreal, Que., 1928, where he was also lecturer in medical research from 1925 to 1929. He was assistant professor of medicine at the University of Pennsylvania School of Medicine, Philadelphia, 1929-1932, and director of the Cox Medical Research Institute, 1932-1936. He is a member of the Committee on Research in Endocrinology, National Research Council.

GEORGIA

State Medical Election.—At the annual meeting of the Medical Association of Georgia Dr. Steve P. Kenyon, Dawson, became president and Dr. Edgar H. Greene, Atlanta, president-elect. Drs. J. Victor Roule, Augusta, and Theodore J. Ferrell, Waycross, were elected vice presidents. Dr. Edgar D. Shanks, Atlanta, will continue as secretary. The session voted to make the Abner Wellborn Calhoun Lectureship a permanent lectureship of the association. For distinguished service to organized medicine and for other activities as well, Dr. Allen H. Bunce, Atlanta, was awarded the Hardman Loving Cup. He has long been an officer of the association and for many years was a member of the Board of Trustees of the American Medical Association. Physicians registered for the meeting numbered 657.

Dr. Warren Heads Physiology Department.—Dr. James V. Warren, formerly associated with Emory University School of Medicine, Atlanta, and during the past year assistant professor of medicine at Yale University School of Medicine, New Haven, Conn., has accepted the appointment as professor of physiology and chairman of the department at Emory. A graduate of Harvard Medical School, Boston, 1939, Dr. Warren has received in competition the "Travel Award" given by the American Physiological Society for the best abstract of a paper that might be read at the seventeenth International Physiological Congress, which is to be held at Oxford, England, July 22-25. This abstract was on a project carried out during Dr. Warren's association with the department of medicine at Emory. He succeeds Dr. J. George Bachmann, who is retiring at the end of the present session.

ILLINOIS

Robert Coghill Cited by University of Kansas.—A distinguished service citation was conferred on Robert D. Coghill, Ph.D., Lake Bluff, Ill., by the University of Kansas in recognition of his public service in conducting research that made possible mass production of penicillin. Dr. Coghill, formerly in charge of the research program of the U. S. Department of Agriculture at Peoria, is now director of research of Abbott Laboratories in North Chicago.

Chicago

Dr. O'Conor Heads Department of Urology.—Dr. Vincent J. O'Conor, associate professor of urology at Northwestern University Medical School, has been appointed chairman of the department to succeed Dr. Louis E. Schmidt, now professor emeritus. Dr. O'Conor, a graduate of Rush Medical College, Chicago, 1917, is chairman of the urology department at Wesley Memorial Hospital and advisory urologist at Chicago Memorial Hospital.

Two Nationally Known Pharmacists Die.—The American Society of Hospital Pharmacists has requested the publication of the following deaths: William J. Gray, chief pharmacist of Presbyterian Hospital, Chicago, for thirty-five years, died Sept. 10, 1946, aged 79. Irwin A. Becker, chief pharmacist at Michael Reese Hospital for forty years, died March 13. These men were known far and wide as advocates of the best in professional pharmacy.

Dr. Harrison Appointed Vice President.—Roland W. Harrison, Ph.D., dean of the division of biologic sciences, University of Chicago, will become vice president of the university and dean of faculties July 1, succeeding Lawrence A. Kimpton, Ph.D., resigned to become dean of students and professor of philosophy at Stanford University August 1. Dr. Harrison became associated with the University of Chicago in 1937 as an assistant professor of bacteriology, becoming associate professor in 1941 and full professor in 1943. He has been dean of the division of biologic sciences since 1944.

Appoint Superintendent at Wesley Memorial.—Ralph M. Hueston, superintendent of Hurley Hospital, Flint, Mich., has been appointed superintendent of Wesley Memorial Hospital, filling the vacancy caused by the death of Edgar Blake Jr. last March. Mr. Hueston has had almost a quarter of a century of experience in hospital administration, beginning at the Galesburg Cottage Hospital in 1924. He came to Austin Hospital, Chicago, in 1926. After ten years at Silver Hospital in Joliet, Ill., he went to Hurley Hospital in 1936. He has been active on the executive committee of Michigan set up to survey that state's hospital program.

Dr. Dragstedt Succeeds Dr. Phemister.—Dr. Lester R. Dragstedt, a graduate of Rush Medical College, 1921, on June 20 was appointed Thomas D. Jones professor and chairman of the department of surgery, University of Chicago, to succeed Dr. Dallas B. Phemister, who will retire July 1 as head of the department which he organized twenty-two years ago. Dr. Dragstedt came to the university in 1921 as assistant professor of physiology. In 1925 he was made associate professor of surgery and in 1930 professor of surgery. He is a founder of the American Board of Surgery. Dr. Phemister will continue at the university as Thomas D. Jones professor emeritus in the department.

INDIANA

Dr. Van Nuys Appointed Dean of Medicine.—Indiana University announced June 14 the appointment of Dr. John D. Van Nuys, 39, member of its medical staff, as dean of the School of Medicine. Since the resignation of Dean Willis A. Gatch last July, Dr. Van Nuys has been executive secretary of the Interim Committee. A graduate of Indiana University School of Medicine, 1936, he has been a director of admissions at the Indiana University medical center, Indianapolis, a director of admissions to the University Hospital and an assistant in medicine at the university.

LOUISIANA

New Director of Leprosarium.—The U. S. Public Health Service has named Dr. Frederick A. Johanson, Carrville, who has been connected with the institute for over twenty years, director of the United States Marine Hospital (National Leprosarium) at Carrville. He will replace Dr. G. A. Faget, former director, who has been ill.

Form State Allergy Society.—The Louisiana State Allergy Society was formed April 1 in Shreveport. The purposes of the society are to further the study of allergy, promote discussion and bring together the allergists of the state. Drs. Bernard G. Efron, New Orleans, was elected president, Henry D. Ogden, New Orleans, vice president and Joseph D. Youman Jr., Shreveport, secretary-treasurer.

MICHIGAN

Plans to Protect Health of Vacationists.—The Michigan Department of Health, Lansing, began June 16 to check up on all sanitary facilities of resort areas which will accommodate millions of summer visitors. Water, food and milk supplies and sewage disposal will be checked, camps and resorts inspected, swimming places approved and polluted lakes and streams posted with warning signs. If sanitary practices are approved, centers bidding for tourist trade will display the sign "Sanitation Approved." The snail eradication program of the Michigan Stream Control Commission is under way for its eighth consecutive year. Swimmers' itch is caused by microscopic larvae that develop in certain kinds of snails. The commission sends men into the northern resort country to apply the snail killing chemicals, but local residents and communities have to furnish the chemicals, as no state funds have been provided for material.

NEW YORK

Rochester Academy Awards.—Dr. Clarence P. Thomas, Rochester, was presented with the Albert David Kaiser Medal at the Rochester Academy of Medicine June 6 on the basis of his war service as chairman of the Medical Defense Committee and the succeeding War Participation Committee Dr. Charles R. Witherspoon was honored with a special citation and a life membership in the academy. Dr. Frank R. Schell, assistant in pathology, Rochester General Hospital, was the recipient of the award presented yearly by Mrs. David B. Jewett for the best case history submitted by a house officer of an accredited Monroe County hospital.

New York City

Cancer Control in Industry.—The Brooklyn Cancer Committee has released its fifth monthly cancer control reminder to 5,000 firms for posting on factory, store and office walls. Each poster deals with a symptom which may be a sign of cancer. Successive titles have been "Why Wait for Pain?", "Have You a Healthy Mouth?", "Can Cancer Be Prevented?", "Have You Indigestion?" and "Don't Hide Those Lumps!"

Personal.—Dr. John L. Rice, New York, former health commissioner of the city, was elected president of the Public Health Association of New York at the annual meeting June 2. ——Dr. Oswald T. Avery, New York, emeritus member of the Rockefeller Institute for Medical Research, received the honorary degree of Doctor of Science at New York University, New York, June 11. The citation read, in part, "pioneer in the chemistry of immunology, whose laboratory conquests have quelled the ravages of . . . pneumonia."

OHIO

Illegal Practitioners.—Found guilty of practicing illegally in Bowling Green, Belle Urban and LaVerne Lemans were each fined $400, with $375 of each fine suspended by the Justice Court of E. E. Bailey in Wood County, on condition that they leave the state. Two unlicensed practitioners, W. R. King and William A. Pierzchala, recently convicted in the Toledo Municipal Court, paid fines after their conviction was suspended by the Court of Common Pleas of Lucas County.

State Health Director Resigns.—Dr. Roger E. Heering, director of the Ohio Department of Health, has resigned to enter private practice in Columbus. In his resignation he pointed out the failure of the general assembly to provide adequate funds for the operation of essential functions and activities in the health department. According to the *Ohio State Medical Journal* the federal government has been giving the Ohio Department of Health twice as much money for current operation as the amount appropriated by the state.

OREGON

Dr. Livingston Heads Department of Surgery.—Dr. William K. Livingston, formerly of Portland, now guest professor at New York University Medical School, New York, will become head of the department of surgery at the University of Oregon Medical School, Portland, August 1, to succeed the late Dr. Thomas M. Joyce. A graduate of the University of Oregon and Harvard Medical School, Boston, he did graduate work in surgery at Massachusetts General Hospital, Boston, and Lakeside Hospital, Cleveland. During World War II he served four years in the navy. He was discharged in 1946 with the rank of lieutenant commander.

PENNSYLVANIA

Society Election.—The Pennsylvania Academy of Ophthalmology and Otolaryngology has announced the following officers for 1947: Drs. Gilbert L. A. Dailey, Harrisburg, president; James J. Monahan, Shenandoah, president-elect; Benjamin F. Souders, Reading, secretary, and Bruce A. Grove, York, treasurer.

Health Poster Contest Reestablished.—The Medical Society of the State of Pennsylvania through its county medical societies has reestablished the annual health poster contest canceled during the war years. Posters submitted by school children in public, parochial and vocational training schools in the state are to illustrate some phase of preventive medicine or general health as related to the family doctor. They will be judged by each component county medical society, and winning posters will be displayed at the annual session of the society in October 1948. Fifteen county societies have already expressed their willingness to conduct elimination contests.

Pittsburgh

Retires as Editor of Pittsburgh Bulletin.—Dr. Walter F. Donaldson, editor of the *Pittsburgh Medical Bulletin* since 1928, retired following the June 28 issue and will be succeeded in that position by Dr. Norman C. Ochsenhirt.

RHODE ISLAND

State Medical Election.—At the annual meeting of the Rhode Island Medical Society in May Dr. Arthur H. Ruggles, Providence, became president, Drs. Isaac Gerber, Pawtucket, vice president; Joseph C. O'Connell, Providence, president-elect; Morgon Cutts, Providence, secretary, and Charles J. Ashworth, Providence, treasurer.

TEXAS

Narcotic Violation.—Dr. Simon I. Dixon, 106 Pacific, Longview, Texas, was convicted in the State Court of Texas of violation of the "Uniform Narcotic Drug Act of Texas" and on April 14 was sentenced to serve a term of two years in the state penitentiary.

Singleton Memorial Fund.—In honor of the late Dr. Albert Olin Singleton, professor of surgery, the University of Texas Medical Branch, Galveston, a special fund has been created for the support of the work of the surgical department at the university. Contributions to the fund may be sent to the librarian of the University of Texas Medical Branch, Galveston.

New Surgical Society.—This recently organized society "to further and maintain high quality and standards among practicing Houston surgeons, to promote scientific knowledge in surgery and to stimulate advanced training in this specialized field" has elected Dr. Henry A. Petersen president, Dr. George W. Waldron vice president, Dr. Granville Q. Adams secretary and Dr. Thomas H. Compere treasurer.

Personal.—Dr. Charles M. Pomerat, professor of anatomy at the University of Texas Medical Branch, Galveston, has gone to Europe as a representative of the Tissue Culture Committee of the National Research Council to attend the International Cytology Congress in Stockholm and the International Physiology Congress in Oxford. While in England, Dr. Pomerat will spend some time in research at the Strangeways Laboratory, Cambridge, with Dr. Honor B. Fell.

Gift for Student Center Building.—The Southwestern Medical Foundation, Dallas, has received a gift of $100,000 for the construction of a student center building as a memorial to the late J. A. Skillern, founder of the Skillern Drug Stores. The gift was made in the name of Mr. and Mrs. Rae E. Skillern and family and the Skillern organization. In making public his contribution, Mr. Skillern said the grant was given in sincere appreciation of his firm's long and pleasant association with the medical and pharmaceutical professions, to whose service his organization is primarily dedicated. Dr. Edward H. Cary, Dallas, president of the Southwestern Medical Foundation, who was informed of the Skillern gift while in Atlantic City attending the Centennial Session of the American Medical Association, stated that the contribution further evidenced the support Mr. Skillern has always given the foundation and its program of advancing medical education and scientific research in the Southwest. "A central student building," he said, "is one of the finest facilities that could be provided for the medical center."

WASHINGTON

Dr. Seelye Appointed Acting Executive Officer.—Dr. Walter B. Seelye, Seattle, has been appointed clinical professor of pediatrics and acting executive officer of the department at the University of Washington School of Medicine beginning July 1. He is a graduate of Harvard Medical School, Boston, and has practiced his specialty in Seattle since 1930.

WEST VIRGINIA

Cancer Control.—The division of cancer control of the state department of health has accepted a total of 1,375 referrals per month, and it is expected that they will increase during the last half of the year. The division has found it impossible to meet the increased cost of hospitalization during the past year. Financial assistance can be extended only to the needy cancer patients who present a good prognosis. The division cannot authorize prolonged hospitalization to incurable cases or assume any financial obligation for treatment or hospitalization of a case until the application has been reviewed and the authorization issued. Services and treatment can be given only at approved treatment centers and tumor clinics. Another source of referral of needy cases has been established through the West Virginia Cancer Society's information centers at Charleston, Clarksburg, Wheeling and Bluefield The division of cancer control also assists in an educational campaign, aids in establishing tumor clinics and provides tissue diagnostic service for needy cancer patients. A binder of cancer bulletins, compiled by the committee on cancer of the Illinois State Medical Society and purchased by the division in West Virginia, will be distributed to all doctors in this state. This literature may be obtained without charge by writing to the Division of Cancer Control, State Department of Health, Charleston.

WISCONSIN

Society News.—At the recent annual meeting of the Wisconsin State Urological Society at Madison Drs. Sidney J. Silbar was elected president, N. Warren Bourne vice president and Charles R. Marquardt secretary-treasurer, all of Milwaukee.

Stovall Award Created by Cancer Society.—The creation of a special award honoring Dr. William D. Stovall, president-elect of the Wisconsin State Medical Society, director of the State Laboratory of Hygiene and former president of the Wisconsin Division of the American Cancer Society, was recently announced by the state division of the society and its lay organization, the Field Army. The award of $250 will be given annually to a Wisconsin resident student at the University of Wisconsin whose primary academic interest is related to cancer. The grant is created as a tribute to Dr. Stovall for many years of faithful service to the organization and in recognition of his accomplishments in developing a public consciousness of malignant growths. The first award was made at a dinner in Madison on May 26 to Mr. Myrton C. Rand, a veteran enrolled in biochemistry.

PUERTO RICO

The Hospital Program.—The financial program recommended by the planning board of Puerto Rico, now approved by the governor and the insular legislature, contemplates an investment of $36,450,000 in new hospitals during the next five years. The hospital survey and construction act, which has been extended to this territory for the construction and enlargement of public and private hospitals, will eventually give Puerto Rico a total appropriation of $12,150,000 over a period of five years. To qualify for this aid the insular government and nonprofit institutions in Puerto Rico would have to provide not less than $24,300,000, according to the financial program. In recommending its program the planning board of this island left a margin of $3,785,000, or 30 per cent of possible federal aid, to be utilized by nonprofit institutions in the construction of new hospital facilities. Allocations of insular funds amounting to $18,230,000 for a five year program to qualify for federal aid is being recommended. Of this amount the legislature voted enabling acts in 1945 and 1946 amounting to $7,165,500. During the current regular session of this body appropriation bills have already been approved to provide the remainder of these insular funds.

GENERAL

Seek Funds to Place Bust in Hall of Fame.—The Society of Tropical Medicine is seeking funds to place the bust of Walter Reed, who led the successful battle against yellow fever, in the Hall of Fame at New York University, to which he was elected Nov. 1, 1945. The university does not have the necessary financial resources. The cost of this work is fixed at $6,000.

Traffic Deaths in Four Months.—In a report on traffic deaths, the National Safety Council, Chicago, said that the death toll was 9,250 for the first four months of 1947. For the four months, the largest city with no traffic deaths was New Bedford, Mass., with a population of 110,300. The second largest was Schenectady, N. Y. (87,500), and Quincy, Mass., (75,800) was third. As the nation enters the vacation season, safer walking and driving were urged by the Council.

American Physiotherapy Association.—This association will hold its annual conference at the Asilomar, Pacific Grove, Calif., July 6-12. Functional anatomy will be under discussion Wednesday, Thursday and Friday with Dr. Verne T. Inman, University of California, San Francisco; Dr. Charles L. Lowman, Orthopaedic Hospital, Los Angeles; Irving Rehman, Ph.D., University of Southern California, and Signe Brunnstrom, M.A., A. P. A., as speakers.

French Periodicals Available for Distribution.—The cultural services of the French embassy have received a collection of recent French periodicals on medical topics intended for free distribution to certain centers throughout the United States, preference being given to college and research libraries, public libraries and special reviews. The number of copies is limited, and requests will be filled in the order in which they are received. A list of available publications will be sent on written request, which should be addressed to Librarian, French Embassy, Cultural Services, 934 Fifth Avenue, New York 21.

World Health Organization.—The Interim Commission has appointed Dr. Thorstein Guthe, formerly assistant to the surgeon general of public health of Norway, to the secretariat as a specialist in venereal disease. Dr. Guthe, a graduate of the University of Oslo, has studied also in London, Paris and Rochester, Minn., and recently completed a year's study at Johns Hopkins University School of Hygiene and Public Health as a fellow of the Rockefeller Foundation. The Committee on Tuberculosis of the association will meet July 30 in Paris; among those on the committee will be Dr. Herman Hilleboe, Washington, D. C., assistant surgeon general, U. S. Public Health Service.

The first meeting of the Expert Committee on Biological Standardization was in Geneva, Switzerland, June 9. The committee is seeking to assure more effective treatment of disease through the use of drugs, serums and vaccines of tested and uniform value. Among those on this committee is Dr. Milton V. Veldee, chief, Biologics Control Laboratory, National Institute of Health, Bethesda, Md.

Special Society Elections.—The new officers of the New England Dermatological Society are Drs. Francis M. Thurmon, Boston, president; Francis P. McCarthy, Boston, vice president; G. Marshall Crawford, Brookline, Mass., secretary, and Mildred L. Ryan, Brockton, Mass., treasurer.——At the recent meeting of the American College of Physicians, Dr. Walter W. Palmer, professor of medicine, Columbia University College of Physicians and Surgeons, New York, was chosen president. Drs. Reginald Fitz, Boston; Francis G. Blake, New Haven, Conn., and Charles T. Stone, Galveston, Texas, were chosen vice presidents.——At the annual meeting of the Medical Library Association, Cleveland, May 27-29, Mrs. Eileen R. Cunningham, Vanderbilt University Medical Library, Nashville, Tenn., was elected president; Miss Janet Doe, New York Academy of Medicine Library, New York, vice president; Dr. Howard Dittrick, Cleveland Heights, Ohio., director, Dittrick Museum of Historical and Cultural Medicine, honorary vice president; Miss M. Edna M. Poole, librarian, Academy of Medicine, Toronto, Canada, secretary.

Large Increase in Births.—In the first quarter of 1947 about 973,000 births were registered in the United States, according to estimates released by the Office of Vital Statistics, U. S. Public Health Service. This is 46.5 per cent more than the 664,000 births estimated to have been registered in the first three months of 1946, and 29 per cent more than the number recorded in the first quarter of 1943, the year which held the previous record number for births. Deaths in this country are estimated to have totaled 388,000 in the first three months of 1947, the same estimated number as that for the first quarter of 1946. The mild epidemic of influenza and other respiratory infections in 1946 increased the number of deaths in January over the number recorded in nonepidemic years. In 1947 influenza increased in March. The provisional death rate for March was higher than for March in any year since 1943. For the first quarter of 1947 the death rate on a cumulative basis was 11.0, or 0.1 per cent less than the comparable rate of 11.1 death per thousand of population (excluding the armed forces overseas) for the first quarter of 1946

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the periods indicated have been received from the division of public health methods, U. S Public Health Service as follows.

Association for the Study of Internal Secretions.—This organization has announced the following awards: The Squibb Award for 1947 has been conferred on Dr. Carl F. Cori and Gerty T. Cori of Washington University, St. Louis, for contributions on the role of hormones in metabolism. The interrelation of hormones and enzymes has been brought into the realm of quantitative chemistry by their brilliant investigations Dr. Cori was also recently awarded the Intermediate Research prize of $5,000 for distinguished achievement in the field of human metabolism by the National Science Fund of the National Academy of Sciences (The Journal, May 31, p 473). The Ciba Award for 1947 has been given to Choh Hao Li, Ph D., of the University of California for his contributions in the separation of hormones of protein nature and the isolation of the growth and adrenocorticotrophic hormones in purified form. The Ayerst, McKenna and Harrison Fellowship for 1947 is awarded to Dr. Samuel Dvoskin of Columbia University College of Physicians and Surgeons, New York, to enable him to continue his studies on the thyroid gland and thyroid hormone assays at Columbia University.

National Board Announces Policy.—The American Board of Obstetrics and Gynecology, in annual session at Pittsburgh June 1-7, announced the following statement of policy "It was never intended by this board that certification should be required by any hospital as a prerequisite to appointment in various staff positions, even though certification or its full equivalent is considered a desirable requisite to appointment in key positions, as on the senior or chief staff, especially of hospitals expecting to conduct approved services for training of residents

"This board does not subscribe to any hospital or medical school rule that certification is to be required for medical appointments in ranks lower than chief of senior staff of hospitals, or associate professorship in schools of medicine, for the obvious reason that such appointments constitute desirable specialist training."

The board also adopted certain changes in regulations as follows·

"Candidates will be hereafter required to present not merely a fundamental knowledge of both branches of the specialty but evidence of actual adequate training in obstetrics and gynecology Credit for graduate courses in the basic sciences which involve laboratory and didactic teaching rather than clinical experience or opportunities will be given credit for the time spent up to a maximum period of not more than six months regardless of the duration of the course"

CORRECTIONS

Charles R. Glenn.—The award of the Legion of Merit noted in The Journal, June 28, page 809, was to Brigadier General Charles R Glenn rather than to Brigadier General Thomas R Glenn General Glenn entered the military service May 3, 1917.

International Spanish Speaking Physicians.—The address of the general secretary of this group, Dr William B P. McDonough, is 1065 Lexington Avenue, New York, rather than 161 East 81st Street, as mentioned in The Journal, June 14

Marriages

Henry Furman Hall Jr, Columbia, S C, to Mrs Ruby Wright Wilson of Fort Bragg, N C, January 24

Albert Lanham Allen, Knoxville, Tenn, to Miss Julia Hodgkin Winn in Orangeburg, S C, March 4

George V Teter Jr, Fort Wayne, Ind, to Miss Mildred Bradshaw of Carbon in Brazil January 18

John Vardaman Gwin to Mrs Sue McQuiddy Bauman, both of Chattanooga, Tenn, Dec 14, 1946.

Louis Donald Tellerman, Chicago, to Miss Nancy Carolyn Bearden of Charlotte, N. C, Dec. 7, 1946

Theodore Tilghman Herring to Miss Jean Corbett Brunson, both of Wilson, N. C, January 11.

Horace D Atkinson to Mrs Pauline H. Hildebrand, both of Lakeland, Fla, in February

Thomas Monroe Wiley Jr to Miss Jane Hearon, both of Birmingham, Ala, March 13

Quentin P. Hamilton, Detroit, to Miss Josephine Warner of Davison, Mich, recently.

William A Graber to Miss Loretta Jane Stapleton, both of Chicago, March 17.

Morris Gottlieb to Miss Theo Dunkelman, both of Atlanta, Ga., January 19.

Max Weis Jr to Miss Bettie Schwab, both of Memphis, Tenn, January 5.

James A. Valone to Miss Ethel Fielder, both of Atlanta, February 4.

Deaths

Frank Dwyer, Bellingham, Wash.; College of Physicians and Surgeons, Baltimore, 1913; member of the American Psychiatric Association; veteran of the Spanish-American War and World War I; served at various times as clinical director and assistant superintendent of veterans' hospitals in Philadelphia, Coatesville, Pa., Northampton, Mass., Kecoughton, and Roanoke, Va., and Togus, Maine; served on the staffs of the East Louisiana State Hospital at Jackson, La., Mendocino State Hospital in Talmage, Calif., state hospitals at Warm Springs, Mont., Yankton, S. D., Fort Steilacoom and the Northern State Hospital in Sedro-Woolley, Wash.; died March 30, aged 67, of chronic myocarditis and arteriosclerosis.

Edward Boynton Angell ⊕ Rochester, N. Y.; University of Pennsylvania Department of Medicine, Philadelphia, 1881; in 1908 member of the House of Delegates of the American Medical Association; a founder and past president of the Rochester Academy of Medicine; served as vice president of the American Neurological Association and the Medical Society of the State of New York; member of the Association for Research in Nervous and Mental Diseases, on the honorary medical staff of the Rochester General Hospital and on the staff of the State Hospital; died in the Julia L. Butterfield Memorial Hospital, Cold Spring, April 23, aged 90, of cerebral hemorrhage.

Alfred Morrell Bidwell ⊕ Tampa, Fla.; Columbia University College of Physicians and Surgeons, New York, 1915; Army Medical School, 1918; vice president of the Hillsborough County Medical Society; past president of the Florida Association of Industrial Surgeons; formerly instructor in surgery at his alma mater and attending surgeon at the Vanderbilt Clinic in New York; served in France during World War I and later as a captain in the regular army; at one time assistant surgeon in the U. S. Public Health Service; on the staffs of St. Joseph's Hospital and the Tampa Municipal Hospital, where he died April 12, aged 58, of coronary occlusion.

Arthur Warren Hayes ⊕ Greenfield, Mass.; Middlesex College of Medicine and Surgery, Cambridge, 1920; specialist certified by the American Board of Radiology; member of the New England Roentgen Ray Society, Radiological Society of North America and the American College of Radiology; for many years member and chairman of the board of health; an associate examiner for the draft board during World War II; on the staffs of the Franklin County Hospital in Greenfield and the Farren Memorial Hospital in Montague City, where he died March 11, aged 56, of cerebral hemorrhage.

Frances Morton Allen, San Diego, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1896; member of the American Medical Association; for many years on the staff of St. Joseph's Hospital, now known as the Mercy Hospital; formerly a member of the city board of health; at one time practiced in Chicago, where she had been on the faculty of the College of Physicians and Surgeons and on the staff of the Lakeside Hospital; died April 13, aged 79, of burns received when her clothes ignited as she attempted to light a stove.

Zachry Martin Abshear, Hazard, Ky.; Hospital College of Medicine, Louisville, 1902; on the staff of the Hazard Hospital; died in the Veterans Hospital in Louisville April 20, aged 73, of arteriosclerosis.

William Carlton Adams, East Taunton, Mass.; Baltimore Medical College, 1896; died March 29, aged 71, of arteriosclerotic heart disease.

Alfred L. Arnold, Owosso, Mich.; Detroit College of Medicine, 1886; member of the American Medical Association; served as mayor; on the staff of the Memorial Hospital; formerly president of the State Savings Bank; died April 19, aged 89, of cerebral hemorrhage.

John Louis Asselin, Detroit; Detroit Homeopathic College, 1906; member of the American Medical Association; for many years on the staff of the Grace Hospital, where he died February 24, aged 67.

Porter Guy Bowen ⊕ San Antonio, Texas; University of Texas School of Medicine, Galveston, 1919; died February 12, aged 55, of cirrhosis of the liver.

William Walker Brandau, Dallas, Texas; Jefferson Medical College of Philadelphia, 1900; member of the American Medical Association; died February 4, aged 75, of intestinal obstruction.

Martin T. Brewer, Des Moines, Iowa; Rush Medical College, Chicago, 1896; served during World War I; major, medical reserve corps, not on active duty; formerly mayor of De Soto, where he had been president of the board of education; died March 27, aged 74, of arteriosclerosis.

Frank H. Carlisle, Italy, Texas (licensed in Texas under the Act of 1907); member of the American Medical Association; died February 8, aged 77, of injuries received when the automobile in which he was driving was struck by a train.

Stark Outtlaw Cherry, Pittsburgh; Temple University School of Medicine, Philadelphia, 1910; died recently, aged 64, of coronary occlusion.

Lemuel E. Clark, Otsego, Mich.; Jefferson Medical College of Philadelphia, 1881; formerly village president and health officer; served on the staffs of the Highland Park (Mich.) General Hospital and the William Crispe Hospital in Plainwell, where he died March 15, aged 91, of senility.

Thomas Alonzo Clark, Memphis, Tenn.; Memphis Hospital Medical College 1907; died in St. Joseph Hospital March 31, aged 66, of intestinal obstruction and strangulated right inguinal hernia.

Robert Clanton Curtis, Calera, Ala.; Memphis (Tenn.) Hospital Medical College, 1901; member of the American Medical Association; local surgeon for the Louisville and Nashville Railroad Company; died in Sylacauga March 24, aged 76, of uremia.

Irving Taylor Cutter, San Antonio, Texas; Harvard Medical School, Boston, 1907; member of the American Medical Association; fellow of the American College of Surgeons; served during World War I; on the staffs of the Nix and Santa Rosa hospitals; died February 18, aged 67, of coronary thrombosis.

Burr E. Decker, Bradford, N. Y.; University of Vermont College of Medicine, Burlington, 1891; since 1920 health officer of Bradford; died March 21, aged 80, of congestive heart failure.

Charles Leslie Edgar, Cleburne, Texas; Fort Worth School of Medicine, Medical Department of Fort Worth University, 1898; member of the American Medical Association; for many years local physician for the Santa Fe Railway; died in a hospital at Temple February 15, aged 74, of complications following a fractured leg incurred in a fall.

Horace Crandell Embry ⊕ Great Bend, Kan.; University Medical College of Kansas City, Mo., 1909; fellow of the American College of Surgeons; on the staff of St. Rose Hospital; died March 13, aged 68, of heart disease.

Gilbert S. Field, Detroit; Detroit College of Medicine, 1891; member of the American Medical Association; at one time on the faculty of his alma mater; died in Grosse Pointe Park, Mich., March 31, aged 79, of cerebral thrombosis and arteriosclerosis.

Charles C. Finney, Atchison, Kan.; Beaumont Hospital Medical College, St. Louis, 1894; served as mayor of Atchison and member of the city council; on the staff of the Atchison Hospital; died in Topeka, March 23, aged 82, of arteriosclerosis.

G. Theodor Fischer, New York; Universität Leipzig Medizinische Fakultät, Saxony, Germany, 1890; died March 8, aged 82, of arteriosclerosis.

Hugh Francis Fisher, Denver; the Hahnemann Medical College and Hospital, Chicago, 1884; University Medical College of Kansas City, 1905; died March 29, aged 84, of cirrhosis of the liver and adhesive pericarditis.

Gustav Henry Frederick, Newark, N. J.; College of Physicians and Surgeons, Baltimore, 1900; died in St. Mary's Hospital, Orange, March 18, aged 74, of chronic myocarditis, nephritis and arteriosclerosis.

Alexander Rutherford Freeman ⊕ Albany, Ga.; Emory University School of Medicine, Atlanta, 1929; interned at the Wesley Memorial Hospital, Emory University; formerly resident physician at the Peter Bent Brigham Hospital in Boston; on the staff of the Phoebe Putney Memorial Hospital; died March 29, aged 42, of cerebral hemorrhage.

George Hartley Gorham, Boston; Tufts College Medical School, Boston, 1903; member of the American Medical Association; died March 12, aged 76, of bronchogenic carcinoma.

William G. Hodges ⊕ Malvern, Ark.; American Medical College, St. Louis, 1912; president and formerly secretary of the Hot Springs County Medical Society; served as president of the state board of health, of which he had long been a member; for many years city health officer; died in St. Vincent's Hospital in Little Rock, March 22, aged 68, of cerebral hemorrhage.

Abby Virginia Holmes, Omaha, the Hahnemann Medical College and Hospital, Chicago, 1899, died March 1, aged 76, of hypostatic pneumonia

George L. Hubbell, Stamford, N Y , College of Physicians and Surgeons, Baltimore 1894, served as county coroner and on the staffs of the Aurelia Osborn Fox Memorial Hospital in Oneonta and the Bathgate Hospital, where he died March 17, aged 75, of cerebral hemorrhage

David Oliver King, Waterloo, Iowa, St Louis College of Physicians and Surgeons, 1909, died February 22 aged 67, of coronary occlusion

Eli Abraham Kusel ⊕ Oroville, Calif , Cooper Medical College, San Francisco, 1895, served as city health officer and for many years as district surgeon for the Western Pacific Railroad, died March 19, aged 72, of arteriosclerotic heart disease and hypertension

Burdette Dudley La Force, Pasadena, Calif , Rush Medical College, Chicago, 1893, fellow of the American College of Surgeons, died March 13, aged 77, of coronary thrombosis

Charles Fred McBurney, Altoona Pa , Jefferson Medical College of Philadelphia, 1897, formerly secretary of the Blair County Medical Society, served as a member of the board of health and on the examining board of the Selective Service during World War I and II, member of the staff of the Altoona Hospital, where he died March 18, aged 72, of heart disease

John Hestain McNutt, Hammond, Ill , Missouri Medical College, St Louis, 1895, served as county coroner, died March 12, aged 77, of cerebral hemorrhage

Harry Markowitz ⊕ Bellevue, Pa , Jefferson Medical College of Philadelphia, 1924, served during World War I, affiliated with the Suburban General Hospital, where he died March , aged 50, of heart failure

erbert S. Martyn ⊕ Cuttingsville Vt , Baltimore Medi olege, 1898, past president of the Rutland County Medical ociety, served as health officer and school director, on the courtesy staff of the Proctor (Vt) Hospital, where he died March 14, aged 75, of carcinoma of the pylorus

Joseph V. Maucher, Carrolltown, Pa , College of Physicians and Surgeons, Baltimore, 1885, died March 28, aged 81, of coronary occlusion

Ezra Gecovia Maxwell, Lexington, Tenn , University of Tennessee Medical Department, Nashville, 1900, member of the American Medical Association, served during World War I, formerly on the staff of various veterans' hospitals, died in the Doctors' Hospital in Jackson, March 20, aged 67, of congestive heart failure and arteriosclerosis

David John Moore, Dexter, Kan , University Medical College of Kansas City, 1892, member of the American Medical Association, on the staff of the Newton Memorial Hospital in Winfield, where he died March 11, aged 82, of aneurysm

Josiah George Moore ⊕ Pomona, Calif , St Louis Medical College, 1889, an Affiliate Fellow of the American Medical Association, fellow of the American College of Surgeons, member of the Missouri State Medical Association, formerly a member of the state house of representatives from Audrain County, Missouri, died March 4, aged 84, of uremia and arteriosclerosis

John Alfred Newnham ⊕ West Palm Beach, Fla , Georgia College of Eclectic Medicine and Surgery, Atlanta, 1914, served during World War I, died in the Good Samaritan Hospital March 19, aged 58, of hemorrhage and arteriosclerosis

Harry Schuyler Nicholson, Pittsburgh, Hahnemann Medical College and Hospital of Philadelphia, 1896, served on the staff of the Shadyside Hospital, veteran of World War I, died in Winter Park, Fla , March 6, aged 77, of heart disease

William Blandine Nies, Fort Worth, Texas, Fort Worth School of Medicine, Medical Department of Texas Christian University, 1916, member of the American Medical Association, Texas Public Health Association, American Public Health Association and the Association of Military Surgeons of the United States, director of the Tarrant County Health Unit, died recently, aged 58, of heart disease

Clifford James Pittman ⊕ Ruleville, Miss , Memphis (Tenn) Hospital Medical College, 1911, served during World War I, died March 8, aged 58, of cerebral arteriosclerosis

Alonzo Thomas Powell, Coeymans, N Y , Albany Medical College, 1889, died in Albany March 8, aged 85, of generalized peritonitis

Harry Herman Rich, Newark, N J , University of Maryland School of Medicine, Baltimore, 1912, member of the American Medical Association, on the staff of the Beth Israel Hospital, where he died March 15, aged 61, of uremia

Charles Cogan Rinard ⊕ Homestead, Pa , Bellevue Hospital Medical College, New York, 1898, past president of the Allegheny County Medical Society member of the board of directors of the Monongahela Trust Company; on the staff of the Homestead Hospital, where he died March 15, aged 71, of aneurysm

Laetus Sanders, Commerce Ga , University of Georgia Medical Department, Augusta, 1897 served on the board of trustees of the State Hospital at Milledgeville, died March 16, aged 73, of myocarditis with congestive failure

Philip Skrainko, St Louis, St Louis Medical College, 1884, died in the Barnes Hospital March 8, aged 75, of coronary occlusion

David C. Stahlman, Potwin, Kan , Kansas City Medical College, 1900, member of the American Medical Association, served as a member of the board of education, died March 6, aged 80, of hypostatic pneumonia following cerebral hemorrhage

Walter Logan Stephenson, Aline, Okla (licensed in Oklahoma under the Act of 1908) member of the American Medical Association, died in St Anthony's Hospital in Oklahoma City February 25, aged 70, of pneumonia following a colostomy

Ethel B. Stribling, Rolling Fork, Miss , Memphis (Tenn) Hospital Medical College, 1901, died in Jackson March 8, aged 68, of heart disease

James Thurman Strimple ⊕ Erie, Pa , Jefferson Medical College of Philadelphia, 1912, served during World War I, for many years member of the board of health of Erie, formerly medical director of Erie County, attending surgeon at the Hamot Hospital and an associate member of St Vincent's Hospital, died March 16, aged 59, of hypernephroma of the right kidney with metastases

George D. Sturtevant, Cleveland, Homeopathic Hospital College, Cleveland, 1887, member of the Cleveland Academy of Medicine, served during World War I, died in February

John William Sugden ⊕ Salt Lake City, Rush Medical College, Chicago, 1923, fellow of the American College of Surgeons, lieutenant, medical corps, U S Naval Reserve, not on active duty, member of the senior staff of the Holy Cross Hospital, died in Phoenix, Ariz , March 19, aged 50, of congestive heart failure

Charles Hill Tait, Philadelphia, Hahnemann Medical College and Hospital of Philadelphia, 1906, died in the Mound Park Hospital, St Petersburg, Fla , March 2, aged 64, of coronary occlusion

Ira Abraham Tawney, Cleveland, Cleveland Homeopathic Medical College, 1903, died March 1, aged 66, of coronary thrombosis

Herbert William Todd, Galion, Ohio, Fort Wayne (Ind) College of Medicine, 1891, member of the American Medical Association, for many years surgeon for the Erie Railroad, director of the First National Bank, died in the Lee Memorial Hospital in Fort Myers, Fla , March 17, aged 75, of empyema of the gallbladder and cardiac decompensation

Burt Dexter Walker, Kalamazoo, Mich , University of Michigan Homeopathic Medical School, Ann Arbor, 1894, member of the American Medical Association and the Kalamazoo Academy of Medicine, on the staff of the Borgess Hospital, where he died March 10, aged 74, of carcinoma of the larynx and arteriosclerotic heart disease

Thomas Weston, Muir, Mich , Detroit College of Medicine, 1893, died in the Blodgett Memorial Hospital in Grand Rapids, March 15, aged 82, of myocarditis

Henry Kirke Wilson, Holbrook, Ariz , Northwestern University Medical School, Chicago, 1890, medical examiner for Selective Service during World War II, formerly affiliated with the Indian Service, died in Winslow recently, aged 73, of cerebral hemorrhage

Henry Mason Wilson ⊕ Peoria, Ill , College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1911, served during World War I and as medical examiner for city Selective Service Board number 3 during World War II, on the staffs of the Methodist Hospital and St Francis Hospital, where he died March 24, aged 59, of influenzal encephalitis and hypertension

Robert S Yancey ⊕ Dallas, Texas, Missouri Medical College, St Louis, 1897, fellow of the American College of Surgeons, member of the staff of the Baylor Hospital, visiting oculist, Parkland Hospital, division oculist, Frisco Railroad and St Louis and Southwestern Railway, chief oculist, Missouri, Kansas and Texas Railway, chief surgeon, Missouri, Kansas and Texas Railroad Employees' Hospital Association, died February 21, aged 74, of heart disease

Action of Folic Acid in Chronic Disorders

The substitution in a diet of saccharose for galactose or lactose (glucides of disequilibrium) produces nervous disorders similar to those brought about by B avitaminosis, but not curable either by yeast or by B vitamins. Chauchard, Mazoue and Lecocq have found that in these disequilibriums a diminution of the nervous chronaxia occurs and later an increase of the muscular chronaxia. They have studied the influence of folic acid on those disorders and reported their results at a meeting of the Society of Biology. They also studied the action of ascorbutic acid on the disequilibrium due to glucides It had no effect on chronaxic disorders accentuated by a diet providing 66 per cent of galactose, but it prevents them in the same way in which folic acid does in an attenuated diet providing 30 per cent of lactose in the rat and the pigeon; in the latter the supplementary factor of the yeasts does not appear necessary any more. These researches demonstrate that folic acid and ascorbutic acid are endowed with a preventive and curative power as regards the chronaximetric disorders in disequilibriums due to glucides, disorders which do not yield to most of the therapies.

Venereal Disease in France

The Bulletin of Epidemiologic Information of the Ministry for Public Health for February 1947 gives the following figures on venereal morbidity during the last two years:

Number of Cases Declared for Each Quarter

	Blennorrhagia		Primary and Secondary Syphilis		Fungating Chancre	
	1945	1946	1945	1946	1945	1946
First quarter	5,769	8,211	2,328	5,190	105	[illegible]
Second quarter	[illegible]	7,790	2,655	4,141	269	[illegible]
Third quarter	10,325	7,257	3,314	3,857	[illegible]	[illegible]
Fourth quarter	9,850	6,468	3,797	3,912	632	136
Totals	34,257	29,856	12,094	17,110	1,195	1,038

Note the decrease of the fungating chancre from 632 cases in the fourth quarter of 1945 to 136 for the same period of 1946. The 1945 increase was due to the influx of North Africa troops. The figures concerning syphilis and blennorrhagia are very high, four times prewar. A slight decline of the cases of blennorrhagia during the fourth quarter of 1946 is due to penicillin having been put at the disposal of practitioners. Some patients have been treated privately and have not been reported, the compulsory declaration of venereal diseases by private doctors being not yet adhered to by all practitioners. The closing of brothels, effected during 1946, has not yet appreciably modified the venereal morbidity. It is estimated in competent circles that, owing to the antivenereal action, the decreasing of the curve should accentuate in 1947.

The League of Red Cross Societies

The Red Cross Societies met in Paris May 21-23 at the International Office of Hygiene under the presidency of Mr. Basil O'Connor, chairman of the Executive Committee; thirty International Red Cross societies were represented, among which were the American National Red Cross, represented by J. T. Nicholson; the Alliance of the Red Crescent Societies of U. S. S. R., by Drs. Zabolotzkaya and Petrowsky, the British Red Cross by Sir John Kennedy, Mr. Hope and other personalities, and the French Red Cross by Ambassador Bargeton, Mr. Truchis de Varenne and others. A conference to take place in Belgrade and designed to assist the war victims of this region has been decided on; also a conference for the revision of the existing convention of Geneva with a view to wartime protection of the civil population. This question will also be placed on the agenda of an international Red Cross conference which is being prepared. As regards the transfer of the head office of the Red Cross, which was in Paris in prewar time and in Switzerland during the war, the question is still under study.

Ten Years of Anti-Scorpion Serum Therapy

At a recent meeting of the National Academy of Medicine, Professor Pasteur Vallery-Radot presented a communication from E. Sergent of the Pasteur Institute of Algeria on the result of ten years (1936 to 1946) of application of anti-scorpion serum therapy. There are fifteen kinds of scorpions in northern Africa, the most dangerous of them being Prionuris australis. For the preparation of anti-scorpion serum, horses submitted to malleinization and vaccinated against tetanus are used. Only the venom of Prionuris australis is used, the serum thus obtained being equally efficient against other northern Africa scorpion venoms. Without treatment, death generally occurs within two to twenty-four hours after the patient has been stung; if symptoms are at once serious, serum is to be injected as soon as possible (before the fourth hour). The doses are 20 cc. subcutaneously or intravenously for adults and 30 to 50 cc. for children, who are more responsive to the venom than adults. In alarming cases several hundred cubic centimeters of isotonic solution of sodium chloride is to be injected simultaneously in another part of the body. The author used serum in 2,209 cases. Out of 531 hopeless cases (134 were at the very point of death), 472 were cured. Protracted toxic phenomena being liable to occur, patients should be kept under observation for several hours and the treatment resumed should toxic symptoms reappear.

Personal

Elected as foreign correspondents to the National Academy of Medicine, second division (surgery, obstetrics, surgical specialties) were Allen Whipple, Wilder Benfield (New York), Sir Webb-Johnson (London), and Brouha (Liége).

BUENOS AIRES

April 15, 1947.

Surgeons Meet in Montevideo

At the Inter-American Congress of Surgery in Montevideo, more than five hundred surgeons of this continent were present. Dr. Alton Ochsner of New Orleans was especially invited. One of the official topics was "Fractures of Pelvis—Treatment and Complications." Drs. Giola, Jorge, Caffardo, Surraco and Lockhardt were speakers. Dr. Ramón Grau San Martin, the president of Cuba, sent an article on "Experimental Diet in Cancer," which was read by Dr. Antonio Glerch Rius, the head of the Instituto de Higiene of Havana.

Price of Drugs

Information given by the authorities on public health shows that the price of about one hundred and seventy-three specific drugs has been reduced in price. The authorities made studies on the expenses of production, showed the results of these studies to the manufacturers and asked them to establish more reasonable prices.

Women in Argentine Universities

Of a total of 21,052 students in universities at the end of 1945, there were 3,030 women. Medicine or its branches is studied by 1,373 at the Faculty of Medical Sciences of Buenos Aires.

New Medical Society

The Sociedad Argentina de Patologia Infecciosa y Epidemiologia was recently established. The president, vice president and general secretary are Drs. Julio Méndez, Carlos Fonso Gandolfo and Julio Hansen, all of Buenos Aires.

Correspondence

CONSTITUTIONAL APPROACH IN THE TREATMENT OF MALE INFERTILITY

To the Editor:—In THE JOURNAL, January 18, in an attempt to forestall useless endocrine therapy where it is not indicated, I wrote on "Endocrine Therapy in Male Sterility of Nonendocrine Origin Valueless." In THE JOURNAL, May 24, Dr. Laman A. Gray apparently took exception to my conclusion, terming it a "nihilistic point of view." Obviously Dr. Gray is a bit confused, since he writes that ". . . Dr. Abner I. Weisman indicated in a communication to the editor that no endocrine therapy was of any value in the treatment of male sterility." If my critic will reread the original correspondence carefully, he will find that I laid particular stress on the inefficacy of endocrines in male sterility of nonendocrine origin.

Secondly, where glandular therapy is indicated and of proved worth I strongly urge its use. On page 234 of my monograph Spermatozoa and Sterility (New York, Paul B. Hoeber, Inc., 1941) one will find the following statement: "In cases where the basal metabolic rate is low, the administration of thyroid gland extract, together with constitutional treatment, has restored fertility to many patients." Certainly, in view of our progress in this field, no thinking physician would preclude thyroid therapy from the individual of hypothyroid tendency who manifests spermatozoal inadequacy. In fact, thyroid extract, of all the endocrine substances, does offer some males their only ray of hope in the glandular approach to therapy.

Since 1942 and in his recent communication to THE JOURNAL, Dr. Gray appears to be highly enthusiastic of the value of gonadotropic substances (particularly equine gonadotropin, gonadogen, Upjohn) in male infertility. He reports better than 50 per cent improvement with this substance. Most investigators unhesitatingly resort to the use of gonadotropic hormones in youths and adolescents with undescended testes, hypogonadism and juvenile Froelich's syndrome. On the other hand, these same authorities (and the list of names is too long to include) have had little effect in the relatively infertile male adult with any of the gonadotropic substances. In fact, back in 1940 I conducted a controlled series of experiments with subnormal males using the same commercial product as did Dr. Gray, which was supplied to me in large quantities by the same manufacturers, and found no definite improvement in semen counts, aside from the variable transient rises and falls which are normally found in semen counts. Therapy with gonadogen was disappointing.

Thirdly, I should like to point out at this time that much can be done to improve the semen output of the male who is of lowered fertility. The outlook for the male whose fertility is not within the normal range is not too depressing if the physician handling the case will treat the individual as a constitutional entity. In supervising the "husband regimen" of hundreds of males and personally analyzing their semen specimens, I am happy to state that there is improvement in spermatozoal output in practically every instance if the patient abides conscientiously by his physician's advice. In treating the male as a constitutional individual rather than as a man who simply possesses testes, most incredible results are obtained. Every effort should be made first to ascertain any underlying physical defect. Similarly, the physician should delve into the patient's psychologic make-up. His general health, his overwork, his lack of rest or sleep, his nervous exhaustion, his improper diet, his mode of life, his occupation, his frequency of sexual relationship—all should be gone into.

A "husband regimen" devised along the lines of improving that particular individual should be worked out. He should be advised concerning his diet—the type of food, the method of cooking his food, the vitamin and mineral-containing foods, and so on. He should be informed about the need for a well regulated mode of living—hours of sleep, proper amount of rest and relaxation, avoidance of excessive physical or emotional strains. He should be told of the deleterious effect of excessive coitus, of excessive uses of alcohol, of overindulgences in general. In essence, the patient who desires to increase his chances of impregnation should be told to care for himself in much the same way as an experienced animal husbandryman cares for a prize bull or sire. There is no question of doubt that in all the laws of breeding the individual who is the most normal and healthy will be able to produce the very best sperm output that he, as an individual, can manufacture.

If the physician treating marital infertility will stress the importance of the constitutional factors in relation to fertility he will find that he will be obtaining a far greater percentage of pregnancies than the one or two which Gray reported in 1942 following the use of gonadogen.

ABNER I. WEISMAN, M.D., New York.

CRUSH SYNDROME

To the Editor:—In reference to the paper by Drs. Corcoran and Page (THE JOURNAL, May 31) it might be of interest to note that during the investigations carried out by the United States Strategic Bombing Survey in Germany in the recent war cases of crush syndrome were encountered in every German city that had been bombed (The Effect of Bombing on the Health and Medical Care in Germany, U. S. Strategic Bombing Survey, War Department, Washington, D. C., Oct. 30, 1945). Thus, one pathologist in Hamburg saw 50 cases in his hospital alone. German scientists referred to the syndrome as decompression shock (entlastungskollaps). It is noteworthy that in several instances victims of crushing injuries were reported to be at home or in hospitals for several days before the signs and symptoms of shock appeared. German air defense medical officers estimated that the mortality of this condition throughout Germany was around 90 per cent and that the remainder recovered without permanent damage to their kidneys. As a matter of fact, most clinicians interviewed were surprised how quickly kidney function returned to normal in some patients with the crush syndrome.

FRANZ K. BAUER, M.D., Los Angeles.

SMALLPOX VACCINATION

To the Editor:—I have your letter asking about a statement made by Walter Winchell that there had been more deaths from vaccination than from smallpox. When Winchell made this statement, he emphasized the fact that it was entirely unofficial. You realize, of course, that in any undertaking as extensive as that of vaccinating over 6,000,000 people, there are bound to be rumors. In New York City there are some 200 deaths a day. Obviously, some of these deaths must occur in people who were recently vaccinated, since practically the entire population of the city was vaccinated. Some people were confusing "death following vaccination" with "death on account of vaccination."

Dr. Rivers feels that a diagnosis of death due to post vaccinal encephalitis cannot be confirmed unless there has been an examination of brain tissue. In 2 cases in which such a diagnosis had been made, autopsy revealed entirely different causes of death.

There have been a number of cases of serious illness and a few deaths which physicians thought might be related to the vaccination. A careful investigation has been made of each case. To date we have no evidence of any death due to vaccination. We shall continue to investigate every case that is brought to our attention.

ISRAEL WEINSTEIN, M.D.
Commissioner of Health, City of New York.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Pardon Does Not Restore Right to Practice Medicine.—The defendant was convicted of practicing medicine without a license, the information charging him with making a diagnosis of one Lewis Janczak as having kidney trouble, with prescribing for said supposed kidney trouble a large quantity of distilled water and with maintaining an office equipped with stethoscope, blood pressure apparatus, examining table, sterilizing cabinet and other equipment. From such conviction, which was affirmed by the Appellate Court, the defendant appealed to the Supreme Court of Illinois.

Among other contentions, the defendant claimed a right to practice medicine because he had been given a pardon by the governor for a prior conviction of manslaughter. It was argued that this restored his rights of citizenship which the conviction had forfeited, including the right to practice medicine. No authorities, said the Supreme Court, are cited by either side as to the effect of a pardon on the rights of a person to engage in a profession, which rights had been forfeited by a prior conviction, nor have we found that the point has been passed on in this state. Two prior Illinois cases have held that an attorney might be disbarred because of conviction of crime involving moral turpitude, notwithstanding the granting of a pardon prior to the institution of disciplinary proceedings. The question of restoration by pardon was not involved, however. In a Florida case, the Supreme Court continued, it was held that an attorney at law was not restored to the right to practice law because he had been pardoned for the offense which had resulted in his being disbarred; and a Washington case held that the pardon of a physician does not restore the right to practice medicine, although it purports to restore all rights and privileges forfeited by the conviction. In the latter case, the court said, "There is a wide distinction between the right which one, whether felon or free, has to hold his own property against the world, and deny even the state the right to take it from him without compensation therefor, and that other right to practice a profession which demands peculiar qualifications in order to protect the public, and requires a license." If a pardon had the effect claimed by the defendant, many persons who have obtained divorces because their spouses had been convicted of a felony would find themselves in an embarrassing position. We are satisfied, the Supreme Court concluded, such pardon does not have the effect claimed by the defendant. Accordingly the judgments of the County and Appellate courts were affirmed.—*People v. Rongetti, 70 N. E. (2d) 568 (Ill., 1946)*

Malpractice: Death Resulting From Allergy to Ether.—The plaintiffs sued for damages for the death of their daughter, which occurred while she was under an anesthetic during an operation being performed by the defendant physician. From a judgment for the defendant, the plaintiffs appealed to the Supreme Court of Washington.

The defendant physician had advised the plaintiffs that their child's visual defect could be remedied only by a surgical operation, so they took the child to the hospital for such purpose. She was given the usual preoperative tests and taken into the operating room at 10:30 the following morning. The anesthetic, ether, was administered by a nurse anesthetist in the employ of the hospital. The defendant commenced the operation at 10:45 a. m. Nothing untoward occurred until approximately 12:10 p. m., when both the defendant and the nurse noticed that the child had become cyanotic, that is, had taken on a bluish discoloration indicating a stoppage of breathing. The defendant immediately stopped the operation and began efforts to resuscitate her. Other doctors were called in to assist, but all efforts were in vain. An autopsy later revealed that the death was caused by an allergy to ether of the child's thymus gland. According to the evidence there is no known test to ascertain the presence of such an allergy prior to the administration of the ether.

The only evidence of negligence which the plaintiffs produced was the following testimony by the child's mother: "Q. After the operation and after you were told of the death of Barbara Jean, did you talk to Dr. Dunnavan? A. After a while yes. We called him out. Q. What did you say to him at that time? A. I accused him of being careless, not giving her the proper examination. Q. Did he say anything in answer to your question? A. He says 'You are right, Mrs. Yeager.'" On appeal the plaintiffs contended that the trial court erred in refusing to submit the case to the jury on the basis of the foregoing evidence.

The Supreme Court said "(4) Before a physician or surgeon can be held liable for malpractice he must have done something in the treatment of his patient which the recognized standard of medical practice in his community forbids in such cases or he must have neglected to do something required by those standards. . . . (8) Negligence on the part of the physician or surgeon by reason of his departure from the popular standard of practice must be established by medical testimony." In the instant case, the Supreme Court pointed out, it was not shown that there was any negligence which was the proximate cause of the unfortunate death. Indeed, the evidence shows affirmatively that the death resulted from an independent cause, that is, an allergy, which was unforeseeable. Accordingly the Supreme Court held that the trial court had not erred in refusing to submit the case to the jury and in directing a judgment of nonsuit. Accordingly the judgment in favor of the defendant was affirmed.—*Yeager v. Dunnavan, 174 P. (2d) 755 (Wash., 1946).*

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL June 28, page 827.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II.* September. *Part III.* Durham, Oct. 21-23. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: Part II. *Oral.* Cleveland, Oct. 5-11. Sec., Dr. P. M. Wood, 745 Fifth Ave., New York 22.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Part I. Oral.* Chicago, Oct. 24-26. Final date for filing application is Aug. 1. *Part II. Written.* Various centers, Sept. 15. Sec., Dr. G. M. Lewis, 66 E. 66th St., New York 21.

AMERICAN BOARD OF INTERNAL MEDICINE: *Oral.* Chicago, Oct. 8-10. Asst. Sec., Dr. W. A. Werrell, 1 West Main St., Madison 3.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: *Oral.* Chicago, May or June. Final date for filing application is Feb. 1. Sec., Dr. W. J. German, 310 Cedar St., New Haven, Conn.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Part I. Written.* Various Centers, Feb. 6. Final date for filing application is Nov. 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh 6.

AMERICAN BOARD OF OPHTHALMOLOGY: Chicago, October 6-12. Sec., Dr. S. Judd Beach, 704 Congress St., Portland, Me.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Part II. Chicago, Jan. 22-23. Final date for filing application is Sept. 15. Sec., Col. F. M. McKeever, 1136 W. Sixth St., Los Angeles 14.

AMERICAN BOARD OF OTOLARYNGOLOGY: Chicago, Oct. 7-11. Sec., Dr. D. M. Lierle, University Hospitals, Iowa City, Ia.

AMERICAN BOARD OF PATHOLOGY: Chicago, Oct. 24-25. Final date for filing application is Sept. 15. Sec., Dr. Robert A. Moore, Euclid Ave. and Kingshighway, St. Louis 10.

AMERICAN BOARD OF PEDIATRICS: Dallas, Dec. 5-7. Philadelphia, Jan. 9-11. Sec., Dr. Lee F. Hill, 718 Royal Union Bldg., Des Moines 9.

AMERICAN BOARD OF PLASTIC SURGERY: Examinations are given in April and November of each year in the home town of applicants. Applications should be sent to Sec., Dr. Louis T. Byars, 508 N. Grand Blvd., St. Louis.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, December. Final date for filing application is Sept. 15. Sec., Dr. Francis J. Braceland, 102-110 Second Ave., S. W., Rochester, Minn.

AMERICAN BOARD OF RADIOLOGY: *Oral.* Boston, Nov. 26-30. Final date for filing application is Aug. 1. Sec., Dr. B. R. Kirklin, 102-110 Second Avenue, S. W., Rochester, Minn.

AMERICAN BOARD OF UROLOGY: Chicago, February. Final date for filing application is Nov. 1. Sec., Dr. Harry Culver, 1409 Willow St., Minneapolis 4.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Attempts to Infect African Green Monkeys by Oral Administration of Poliomyelitis Virus. H. A. Howe and D. Bodian.—p. 223.
Rise and Decline of Poliomyelitis Virus Levels in Infected Nervous Tissue. D. Bodian and Mary C. Cumberland.—p. 226.
*Poliomyelitis Virus in Urban Sewage in Epidemic and in Nonepidemic Times. J. Melnick.—p. 240.
Effectiveness of Various Rodenticides on Populations of Brown Rats in Baltimore, Maryland. J. T. Emlen Jr. and A. W. Stokes.—p. 254.

Isolation of Poliomyelitis Virus from Throats of Children.—An outbreak of poliomyelitis in Baltimore in the summer of 1944 gave Howe and Bodian the opportunity to make observations on the presence of poliomyelitis virus in the throats of persons who had had varying degrees of contact with patients with paralytic poliomyelitis. Poliomyelitis virus was isolated from the throats of 1 of 3 patients with poliomyelitis and from 1 of 6 juvenile family contacts, but not from 5 adult familial, 7 juvenile or 6 adult extrafamilial contacts of these patients. Virus was present in the throats of at least 2 of 28 healthy children from a neighborhood playground. One year later these children were shown to have antibody against the viruses isolated from them.

Poliomyelitis Virus in Sewage.—Melnick describes further tests for poliomyelitis virus in the sewage from two urban areas. During the 1943 epidemic in Chicago, poliomyelitis virus was detected in the effluent from Imhoff settling tanks on two occasions seventeen days apart. Virus was also found in raw sewage at a plant serving another part of the city, in sewage leaving a hospital with poliomyelitis patients, and in sewage collected from a residential area in which no persons with manifest poliomyelitis were living at the time and in which none subsequently developed. When the epidemic subsided all sewage tests were negative. Monthly tests for poliomyelitis virus in New York City raw sewage have been carried out from 1940 through 1945. In four of the six years virus was detected in the sewage. In one of the two years when virus was not detected no cases of poliomyelitis were reported in the area. Virus was detected only in late summer and fall months in New York. Calculations show that in Chicago 6,000,000 monkey infectious doses of virus were leaving a sewage disposal plant per minute at the time of collection and that in New York 500,000 doses per minute were entering a sewage collection station. A 100 Gm. stool may contain 10,000 monkey infectious doses of virus.

Rheumatic Fever in Children: Clinical and Laboratory Diagnostic Criteria. L. M. Taran.—p. 368.

Excretion of Benzoyl Glucuronate as Liver Function Test.—Snapper and Saltzman describe a simple liver function test which is based on the presence of excessive excretion of benzoyl glucuronate in the urine after ingestion of 5 Gm. of benzoic acid. The test was studied in 23 normal volunteers, in a control series of 100 patients who had no obvious hepatic disturbances and in 89 other patients in whom hepatic disturbances were suspected. In normal volunteers and in patients without hepatic disturbances the test was negative. The test was positive in all cases of hepatitis and portal cirrhosis. The test was positive also in some patients with thyrotoxicosis and in most cases of hepatic metastasis. It was negative in all of nine lymphomas. In 2 cases of early type postarsphenamine jaundice hepatocellular damage was indicated by positive tests. The glucuronate reactions remained negative in a patient with obstructive jaundice of long standing.

33:177-334 (April) 1947. **Partial Index**

**Some Clinical Observations Concerning Noma.* C. C. Wang Sung and R. Y. Sung.—p. 284.
Premedication by Co-Medication in Local Anesthesia. S. I. Copen.—p. 290.
Master Metal Facial Cast for Swaging Lead Masks in Treatment of Carcinoma of the Skin of Face. S. G. Castigliano and P. P. Gross.—p. 319.

Noma.—Wang Sung and Sung report 30 cases of noma admitted to the Dental Clinic of West China Union University. Noma is not a disease by itself but is a terminal sign of some debilitating disease such as measles, dysentery or leukemia. There is no specific treatment for noma. Measures to restore the vitality of the patient and reestablish oral and general cleanliness appeared to be most effective. Milk, orange juice, cod liver oil, yeast, meat broth and green vegetables were fed in large quantities. Necrotic tissue, hopelessly affected teeth and alveolar sequestrums were removed gently. The mouth was irrigated with potassium permanganate solution 1:1,000 twice a day and rinsed with warm saline solution every thirty minutes, not to obtain a germicidal effect but to remove sloughs and bacteria. Acriviolet 2 per cent applied topically was found effective. Blood transfusions revitalized dangerously ill persons

Mycphagism Congenita. W. A. Dalman.—p. 494.
Use of Tantalum for Facial and Cranial Defects. J. Newman.—p. 499.
Strictures Following Transurethral Resection: Comments on Indication for Operation. J. J. Stratte and J. Stratte.—p. 503.

Intestinal Decompression Tube.—By using a single lumen long intestinal decompression tube with a mercury weighted balloon tipped head Cantor and his associates have been able to intubate successfully all but 8 of 200 patients with intestinal distention. The head of this tube constitutes the propulsive mechanism. The only cases in which intestinal intubation alone can be safely used are cases of adynamic ileus or cases in the inflammatory distention group. The use of the intestinal decompression tube as a preliminary to bowel resection or anastomosis obviates the necessity for enterostomy and hence reduces the risk to the patient. Intestinal intubation should be entrusted only to one who understands the mechanism involved in the passage of the tube; that is, the surgeon. Intubation should not be relegated to the intern or nurse, because in the hands of the novice the long intestinal decompression tube is a dangerous instrument.

Tuberculin Testing in Student Nurses. M. N. Shoor.—p. 177.
Method of X-Ray Reproduction of the Negative X-Ray Film. A. Rest and Leona Stroud.—p. 184.

Promizole Treatment of Miliary Tuberculosis.—According to Milgram and her associates the sulfones promin, diasone and promizole, which have a great influence on experimental tuberculosis of guinea pigs, are far less effective in clinical tuberculosis. They administered promizole to 5 children with miliary tuberculosis. Three of these have survived twenty-four to twenty-seven months since the diagnosis was made. The primary chest lesions cleared very slowly and incompletely. Kidney and spine lesions appeared and progressed under continuous administration of the drug. Promizole has bizarre toxic effects on the thyroid gland, breasts and genital hair. These are more likely to appear after prolonged administration.

Carcinoma Simulating Pulmonary Tuberculosis.—Siltzbach shows that industrial mass roentgenologic surveys which include many persons above 40 years of age are bringing to light silent lung carcinomas. He presents the histories of 2 patients with such neoplasms. The first patient was sent to a tuberculosis institution, but since he remained free from symptoms and the lesion appeared unchanged he was discharged with the disease considered arrested after an eight weeks stay. He returned to work and continued to feel well. Five months later he felt a dull pain in the right scapular region. A chest film showed increase in the size and density of the lesion. The borders were sharper and the diameter measured about 4 cm. The fingers showed early clubbing and it was thought that the patient had a bronchial carcinoma. The chest was explored and a mass the size of a walnut was palpated in the posterior portion of the right upper lobe. This lobe and the right middle lobe, which adhered firmly, were extirpated. The tumor proved to be an epidermoid carcinoma. There has been no evidence of recurrence of the neoplasm for two years following the operation. The second patient was considered tuberculous for sixteen months before the true nature of the pulmonary process was realized. This patient died sixteen hours after operation. The author suggests early exploratory thoracotomy when the diagnosis is equivocal.

Teeth as Source of Headache.—Robertson and his associates studied the effects of noxious impulses experimentally induced and of those arising from morbid processes. The initial pain induced experimentally and felt locally in a tooth had both a burning and an aching quality. The pain secondarily experienced in the head was of two varieties: (1) that due to central spread of excitation and experienced in tissues supplied by the same and adjacent divisions of the fifth cranial nerve and (2) that due to sustained contraction of the muscles of the head and neck resulting secondarily from noxious stimuli arising in the teeth. All the pain experienced remote from the site of noxious stimulation in a tooth was of a steady aching quality and was eliminated by infiltration of monocaine hydrochloride about the primary source of noxious stimuli except that secondarily arising in the muscles of the head and neck as the result of sustained muscular contraction. This component slowly decreased, usually after several hours. Following a period of spontaneous or experimentally induced noxious stimulation in a tooth, the pain threshold of the latter was appreciably lowered until ordinarily inadequate stimuli caused both local and remote pain. Noxious impulses arising from the teeth and associated with headache, although clinically important, are not a common cause of headache.

Penicillin in Diphtheria.—Peterson thinks that no definite conclusion can be drawn as to the status of penicillin in the treatment of diphtheria from the few cases reported in the literature. Although most laboratory work done in vitro suggests that penicillin might be effective in the treatment of this disease, laboratory work on experimental animals fails to bear this out. However beneficial its use might prove to be in inhibiting the growth of diphtheria organisms, penicillin could have no neutralizing effect on the free toxin already in the circulation and the tissues. Partial inhibition of the diphtheria bacilli does not stop the production of toxin. With present knowledge of this drug it can be recommended for use only in the treatment of carriers and of patients whose infection is persistent and who have not responded to adequate amounts of antitoxin.

Exchange Transfusions in Erythroblastosis Fetalis.—Wiener and his associates describe 2 cases of erythroblastosis which were treated by the method of exchange transfusion. This method entails the use of heparin, the injection of the donor's blood into the saphenous vein at the ankle, and the withdrawal of the infant's blood through the radial artery at the wrist. Of 17 infants treated by this technic all but 1 made a prompt and lasting recovery. This demonstrates the effectiveness as well as the safety of the procedure.

Psychiatric Needs of General Hospitals. P. E. Huston and J. S. Gottlieb.—p. 163.

Action of Choline in Cirrhosis of Liver and Related Conditions.—Paul and his associates studied patients with diabetes mellitus, cirrhosis of the liver, multiple sclerosis and a miscellaneous group of pathologic conditions in which abnormal fat metabolism is a factor. The diabetic patients receiving choline showed more nearly normal lipid levels than a control group. Low lipid levels were found in cirrhosis, and choline produced a definite increase in the blood lipid levels in a significant number of these. In general, choline therapy improved the blood lipid picture whenever abnormalities existed previous to its administration. A correlation existed between the laboratory findings and the subjective responses to the administration of choline. All subjects noted an increased sense of well being, an improved appetite and an increase in vigor. Both the objective and the subjective results of choline therapy support the importance of this drug and of lipotropic agents in general in treatment of conditions related to abnormal fat metabolism.

Vaginal Smear in Diagnosis of Gynecologic Cancer.—Brown and his associates took vaginal smears from women with and without symptoms suggestive of cancer. Among 65 women with bleeding and discharge there were 16 with positive, 9 with suggestive and 40 with negative vaginal smears. Of 103 without symptoms, 3 had positive and 4 suggestive smears. In a group of 25 women who had previously been treated for carcinoma and had returned for routine checkup, clinical examination revealed recurrence in 14, and the vaginal smear was in agreement 13 times. The smears from the 11 women who showed no clinical evidence of recurrence were negative in 10 instances. It is proposed to screen all women over 30 entering the University Hospital and the female inmates of the state institutions.

Methylcellulose and Bacterial Motility.—*Pijper* shows that solutions of methylcellulose provide a suitable medium for the study of bacterial motility. Such solutions possess sufficient viscosity to slow down the movement of otherwise fast moving bacteria and thus supply conditions for detailed observation. The special advantage of methocel over the solutions of gelatin and gum used heretofore for this purpose is that the precipitation of the colloid material on bacterial bodies and appendages is minimal, so that motility is not hindered by this thickening. Solutions can be prepared in which for a long time the amount precipitated on the bacteria is just enough to make the fine appendages ("flagella") visible by ordinary dark-ground methods with ordinary lamps. Methocel therefore places the dark-ground study of bacterial motility and bacterial appendages during life within the scope of ordinary microscopic technic.

Partial Nephrectomy for Calyectasis with Stone.—Engel reviews 9 cases in which partial nephrectomy has been done for calyectasis with stone and the patients followed for five or more years. The operation is indicated in all cases in which stones are present in dilated calices with evidence of infundibular constriction and is especially applicable when this involves the upper or lower calices, the remainder of the pelvis being essentially normal. The removal of the pathologic calix reduces the chance of recurrent stone. No recurrence has been observed in any case in this series for from five to twelve years after operation. Infection in the kidney cleared up after operation. The intervention carries no greater risk or morbidity than other operations for kidney stone.

Surgical Approach to Renal and Other Retroperitoneal Tumors.—Sweetser describes his scheme for an extraperitoneal approach to renal tumors and stresses that surgery for any mass in the kidney or retroperitoneal tissues should be undertaken with recognition of the possibility of cancer. Exploration is begun through an oblique incision in the flank, and only when cancer is demonstrated is the incision extended. The incision described preserves the nerve supply of all the abdominal muscles. The unopened peritoneum helps in control and retraction of the intraperitoneal organs and protects them from infection and from damage by evaporation and by trauma of packs and retractors. The lateral posture of the patient and shape of the flap result in better exposure than any other approach because the abdominal contents drop away toward the opposite side with little or no need for retractors, and the area of the renal vascular pedicle comes well up into the wound for accurate and adequate primary treatment.

Anterolateral Chordotomy for Intractable Pain in Interstitial Cystitis.—Many patients with interstitial cystitis can be kept reasonably comfortable with a variety of therapeutic methods, but some eventually become refractory and for these Nesbit recommends anterolateral chordotomy. Although chordotomy interrupts the upper sensory neurons concerned with the conduction of pain impulses, it does not interfere with the pathways that mediate the sensations of touch or distention and it does not interfere with the primary reflex arc that controls the bladder. The upper motor neuron remains intact. The patient should be able after chordotomy to urinate at will and with normal micturitional control and should be able to empty his bladder completely. Bilateral anterolateral chordotomy in 2 patients relieved the intractable pain of interstitial cystitis that was refractory to all forms of treatment, including sympathectomy. A remarkable feature in 1 case was that the typical lesions of interstitial cystitis have apparently healed completely. The second patient reported that he was free from bladder pain and that he had normal micturitional control and no nocturia. His sexual function seems to be entirely normal. The preservation of sexual function in the male patient was unexpected. The results obtained in these 2 cases suggest that chordotomy is a logical procedure in advanced interstitial cystitis, but the seriousness of the operation should limit its use to refractory cases alone.

*Pompholyx and Its Treatment. B. Schuster.—p. 298.

Treatment of Pompholyx.—Pompholyx (dyshidrosis cheiropompholyx) is an acute or subacute skin disease occurring on the hands and feet, characterized by sago-grainlike deeply embedded vesicles and occasionally bullae which may become pustular. They have a tendency to recur during warm weather. Systemic reactions are usually mild, but general malaise may be present and the usual complaints are nervousness, irritability and depression. The therapy of pompholyx has been so disheartening and unsatisfactory that many patients with this condition have long since given up hope of receiving satisfactory relief. Schuster says that Benedek cultured a sporogenous bacillus from closed, intact blisters of pompholyx which he called B. endoparasiticus. He developed a vaccine and used it successfully in the treatment of the disease. Schuster reports several cases in which he used Benedek's vaccine. Of 17 cases treated, 13 were considered therapeutically successful. The average number of injections in those responding to Benedek's vaccine was eight.

Adenomatous Goiter Without Hyperthyroidism.—Buckwalter and his associates sent out questionnaires to members of the medical and surgical departments in a number of medical schools inquiring as to management of patients with nontoxic nodular goiter. Questionnaires were sent also to 374 patients with nontoxic nodular goiters seen at the University of Iowa Hospitals. Fifty-nine per cent of the patients who had been operated on were improved, while only 8 per cent of those not operated on were improved. The nodular goiter, usually referred to as nontoxic, is often associated with symptoms of nervousness and irritability, palpitation, tachycardia and loss of weight. These symptoms are present when the basal metabolic rate is within normal limits. Surgery is indicated for this group of patients because it will result in relief of symptoms in a significant percentage of cases.

Gastric Resection for Peptic Ulcer.—An earlier review of 50 consecutive gastric resections for peptic ulcer, performed between 1927 and 1940, convinced Bartels and Dulin that their postoperative mortality was too high, that their indications for resection were too limited and that the recurrent ulcer rate was too great. In 100 resections performed from 1941 to 1943 inclusive the postoperative mortality rate was reduced from 28 to 8 per cent. In a further series of 121 resections done in 1944 and 1945 it was further reduced to 1.6 per cent. Radical resection of the stomach did not increase the mortality rate. The indications for resections in peptic ulcer have been extended, as is evidenced in the increasing number of resections performed. The recurrent ulcer rate has been reduced from 14.7 per cent in the first 50 gastric resections to 4.3 per cent in the 92 survivors of the 100 resections performed between 1941 and 1943. There are no known recurrent ulcers in the 119 survivors who were resected in 1944 and 1945. Recurrent ulcer was more frequent after conservative than after radical resection. A relative achlorhydria is necessary to prevent recurrent ulcer.

Para-Aminobenzoic Acid in Rocky Mountain Spotted Fever.—James and Walker present the histories of 4 patients with Rocky Mountain spotted fever in whom they employed para-aminobenzoic acid. The first patient was a Negro woman aged 49 who was given an initial dose of 8 Gm. on the fourth hospital day and then 2 Gm. every two hours. Three days after the para-aminobenzoic acid was started her delirium cleared, the fever lessened and her appetite returned. After this she improved rapidly, and the medication was discontinued after ten days. She was able to give a history of a tick bite before being taken ill. She was discharged as being cured on the twenty-first hospital day. The other 3 patients likewise recovered after treatment with para-aminobenzoic acid. The authors believe that this drug exerts a definite therapeutic effect on Rocky Mountain spotted fever in both modifying its severity and hastening recovery.

Parotidectomy.—Bailey states that a mixed parotid tumor remains curable for years, sometimes for a decade or more, yet because of misconceptions concerning its behavior and its treatment it is allowed to pass from curability to an incurable malignant condition. After discussing the bogey of facial palsy and the illusion of enucleation, the author gives his attention to operative details. Surgical operation in the parotid region has been stultified by the instructions surgeons receive from anatomists. Bailey calls attention to an excellent illustrated description of the true anatomy of the parotid gland and its relationship to the facial nerve given by members of the Department of Anatomy of the University of Chicago. Nearly all parotid tumors are completely radioresistant. If various misconceptions were swept aside and if general surgeons would devote time and attention to parotidectomy, parotid tumors would take their place among curable tumors.

Added Infections in Burns.—Colebrook and his associates say that during a twelve months period involving more than 1,400 dressings cross infection by hemolytic streptococci, Pseudomonas aeruginosa and Proteus vulgaris introduced while dressing burns has been almost entirely eliminated by doing the dressings in a dust free atmosphere, using a strict aseptic technic and using a penicillin-sulfathiazole cream as a routine application. During the same period a few added infections by these three organisms have occurred (33 in all), but most of these added infections occurred in patients whose burns had been imperfectly covered before they were redressed. The incidence of added infection in burns which were found to be imperfectly covered when they arrived for redressing was ten times as high (8.6 per cent) as that of the burns which had perfect cover throughout the period between dressings (0.8 per cent). Among the 224 patients admitted without streptococcic infection only 12 acquired this infection during their stay in the hospital, and the clinical effect of these few added infections was practically nil. The problem of controlling added infections of burns with Staphylococcus aureus remains untouched. These infections, which are numerous, may well play a prominent part in the slow healing of burns during the later stages of recovery.

Hypertensive Headache Treated with Potassium Thiocyanate.—Mills used potassium thiocyanate in the treatment of 27 cases of benign hypertension in which headache and giddiness were prominent symptoms. Besides these, 8 cases of benign hypertension, presenting with symptoms other than headache and giddiness, and 10 cases of malignant hypertension were treated. The conclusion reached is that this drug has a definite but limited place in the treatment of hypertension and should be restricted to cases in which hypertensive headache is a predominating and troublesome symptom and does not respond to simpler forms of therapy. This drug does not affect the course of the disease nor does it permanently lower the blood pressure, even in cases in which there is much symptomatic improvement. Potassium thiocyanate should be regarded purely as a palliative.

Treatment of Anuria Following Intravascular Hemolysis.—In the case described by Dobbs a soldier appeared to be dying of extreme oliguria and uremia following massive hemolysis after transfusion. Decapsulation of one kidney under spinal anesthesia was followed by an immediate diuresis, which reached a maximum in ten days, and by a more gradual return to normal of urine and blood urea level and by eventual recovery. Improvement probably cannot take place until diuresis sets in; consequently, when decapsulation is contemplated, it should be undertaken early. The case presented here was 1 of 8 in which decapsulation was done, with recovery in 7, whereas of 46 treated conservatively 31, or about two thirds, were fatal. Unilateral decapsulation appears to be sufficient and is probably followed by diuresis and eventful recovery in both kidneys. Rapid diuresis but slow recovery of the concentrating power of the kidney suggests that anuria and tubular damage have a separate etiology. Tubular damage is sustained as the toxic products of hemolysis pass down and are concentrated in the tubules. Raised intrarenal tension possibly plays its part in the production of anuria, but a more satisfactory explanation is that it is reflex in origin and that decapsulation is effective by removing sympathetic nerve impulses. The spinal anesthesia used in the operation of decapsulation may be a factor in initiating diuresis. Splanchnic block would be a more satisfactory method and has been used with success in reflex anuria and in transfusion kidney.

Palpable Epitrochlear Glands in Syphilis.—According to Martin there is a belief that enlargement of the epitrochlear glands is suggestive of syphilis in the stage of general adenitis which precedes secondary skin eruptions. Palpable epitrochlear glands were so commonly observed in soldiers during the late war that the author made a survey to define their normal limits of size and their incidence in adult males. A survey comprising 200 soldiers and 100 male civilians between the ages of 16 and 50 showed that epitrochlear glands were palpable in about 40 per cent. Of the palpable epitrochlear glands, 14 per cent exceeded the size of a cherry stone. Appreciation of these normal limits is essential before describing a palpable epitrochlear gland as enlarged or pathologic. There is no reliable evidence to support the belief that enlarged epitrochlear glands are more characteristic of syphilis than of other diseases which cause glandular enlargement.

Revaccination in Adults.—Broom says that during 1945 civilians were recruited by UNRRA to administer the camps then being set up in northwestern Europe for "displaced persons." On the assumption that the risk of infection would be high in these camps it was decided that every member of the staffs who did not possess a certificate of vaccination less than a year old should be vaccinated against smallpox. A series of 1,227 adult revaccinations against smallpox is described. Details are given of the method of vaccination, including the insertion of killed virus as an indicator of sensitivity to vaccine lymph.

Sensitivity reactions are shown to develop at all intervals and to be unrelated to immunity. It is suggested that these reactions lead on occasion to misinterpretation of the response to vaccination. Attention is drawn to the lack of provision in the international certificate of vaccination against smallpox of a category to include persons who are insusceptible to vaccinia but do not show the reaction of immunity; an alternative method of certification is proposed.

Importance of Bronchial Lesions in Patients with Pneumonoconiosis. W. Bruninx.—p. 536.

Agonal Bacteremia in Human Subjects.—Millet and his associates studied the problem of agonal bacteremia by blood cultures in dying patients and observing body invasion early after death. They conclude that invasion of the blood stream by intestinal microbes during agony occurs in only a few instances when the natural immunity is low.

Malignant Exophthalmos Following Treatment with Thyroid Inhibitors.—Bastenie and Tagnon present the histories of 2 patients who developed toxic diffuse goiter after treatment with thyroid inhibiting substances. One of the patients had been treated with aminothiazole and the other with thiouracil. These observations prove the dissociation between the toxic and the ocular symptoms of toxic diffuse goiter. In both patients severe exophthalmos developed after the basal metabolism had returned to normal or below it. What makes the 2 cases especially noteworthy is the rapid appearance of palpebral edema, chemosis and ophthalmoplegia. The exophthalmos subsided on discontinuance of the thyroid inhibiting medication and administration of small doses of thyroid.

Genesis of Generalized Edema: Role of Chloride. *Catherine Kousmine.* —p. 290.

Thiomidil (4-Methyl-Thiouracil) in Hyperthyroidism.—Spühler maintains that thiomidil, 2-thio-4-methyl-6-oxypyrimidin, was somewhat less toxic and more effective than thiouracil in the treatment of 50 cases of thyrotoxicosis. The doses required are smaller with this preparation than with other thiourea derivatives. In order to avoid the development of myxedema as the result of excessive doses, the basal metabolism must be tested at regular intervals or the blood cholesterol must be ascertained. The struma may become harder and larger as the result of excessive doses, but these changes rapidly disappear after the drug is discontinued. At the onset of the medication there may be excitation and nausea, but these subside quickly and do not necessitate interruption of the medication. Although no cutaneous eruptions or granulocytopenia were observed, watch must be kept for the possible development of agranulocytosis. Thiomidil should not be given to pregnant women because it rapidly passes to the fetus and may cause damage. Medication with thiomidil increases the sensitivity to digitalis and strophanthin, so that previously ineffective doses become active.

*Hemorrhage in Liver Cirrhosis. J. Flores Espinosa.—p. 253.

Hemorrhages in Liver Cirrhosis. — Flores Espinosa observed 275 patients with liver cirrhosis at the Hospital General de Mexico City during a period of three years. A necropsy was performed on 49 patients. The cause of death in 25 cases was massive fatty degeneration of the liver. In 11 patients who died of acute anemia following acute or repeated gastrointestinal hemorrhages, bleeding was due to ulcerated gastric or esophageal varices and less frequently to multiple ruptured capillaries of the gastric mucosa and submucosa and to blood dyscrasia of the type of purpura due to metabolic disorders of the C and K vitamins. Clinically the hemorrhagic tendency is manifested by blood spitting or by small gingival and subcutaneous hemorrhages, hematuria and gastrointestinal hemorrhage. The bleeding time and coagulation time are prolonged, the prothrombin time shortened and the number of blood platelets diminished. The therapy of gastrointestinal hemorrhage in cirrhosis is preventive. It consists in administering a diet rich in proteins, carbohydrates and vitamins and poor in fats. Insulin, dextrose, liver extracts, local diathermy of the hepatic region, choline and methionine also are indicated.

Electrocardiogram in Typhus. L. Norviit.—p. 565.

Does Poliomyelitis Virus Grow in Sewage?—Evans presents data which suggest that the number of carriers of poliomyelitis virus in the population during times of moderate incidence of poliomyelitis must frequently approximate 1 per cent. If 1 per cent of the population is excreting poliomyelitis virus at a given time, and if a 1,200 cc. sample of sewage contains 0.5 to 1.5 Gm. of feces, this amount of sewage will contain, on the average, 5 to 15 mg. of feces from excretors of virus. It might reasonably be expected to infect monkeys with occasional specimens of this small size. Therefore the finding of poliomyelitis virus in sewage is compatible with the results that might be expected on the basis of contamination from carriers of virus. The growth of virus in protozoa or other micro-organisms of sewage is not essential to explain such isolations. However, such growth of virus, or the simple harboring of virus by micro-organisms in sewage, cannot be excluded.

*Treatment of Hernia of Nucleus Pulposus or of Prolapse of Intervertebral Disk. A. C. de Vet.—p. 493.

Hernia of Nucleus Pulposus.—According to de Vet it is possible to differentiate between prolapse of the intervertebral disk in which pressure of the nucleus pulposus drives the annulus fibrosus outward and the typical hernia in which the tissue of the nucleus pulposus perforates through an opening in the annulus fibrosus into the vertebral canal. As a rule in case of prolapse backache predominates, whereas in the presence of hernia symptoms of sciatica are most pronounced. Since prolapse and hernia may be combined, symptoms of backache and sciatica may be present. The classic complaints of chronic low back pain and sciatica may become intensified as the result of mechanical influences and by hydrodynamic factors. The clinical examination does not always permit a correct localization; in these cases myelography is indicated. Surgical intervention should never be adopted unless conservative therapeutic measures have been applied. Absolute rest is one of the most successful methods of conservative treatment. The extradural approach is highly preferable to the transdural one, but the latter cannot always be avoided. It should be accepted as a rule always to examine both sides of the disk.

Book Notices

The Treatment of Diabetes Mellitus. By Elliott P. Joslin, A.M., M.D., Sc.D., Medical Director, George F. Baker Clinic, New England Deaconess Hospital, Boston, and others. Eighth edition. Cloth. Price, $10. Pp. 861, with 13 illustrations. Lea & Febiger, South Washington Square, Philadelphia 6, 1946.

Joslin's textbook on diabetes mellitus, now in its eighth edition and expanded by the collaborative effort of his associates, is undoubtedly the best known book on the subject. It has become encyclopedic in its scope, recording not only the extensive clinical experience of its authors in the George F. Baker Clinic in Boston but referring impartially to most of the relevant work of others. Such an imposing array of facts concerning one disease is a monument to the painstaking effort of the group who have collected and organized them, and especially to the senior author.

The title of this book has always remained "The Treatment of Diabetes Mellitus." Except for the wisdom of preserving the original title it is somewhat misleading, because the breadth of coverage of the book goes far beyond therapeutics. Everything of any interest related to diabetes mellitus is described completely and accurately, in a well organized manner and with the insight and interest that only clinicians who have studied thousands of patients and most of the pertinent experimental and clinical literature can accomplish. For many practicing physicians, students and interested laymen the volume has become a veritable Bible on diabetes.

The new edition is revised with elaborate thoroughness, retaining most of the authors' statistical data and fundamental concepts regarding the disease and at the same time adding all new and important developments since the previous edition. The sections on alloxan diabetes, degenerative complications, insulin modifications, pregnancy and related endocrine disorders are revised from a particularly modern point of view.

In addition to the well known sections by the chief author, Drs. Root and Marble have each written or contributed to eight chapters out of thirty-one, and Drs. White and Bailey each five. Associated diseases such as cancer, syphilis and tuberculosis, as well as neurologic, hematologic, cutaneous, genitourinary, allergic and surgical disorders are covered with exhaustive thoroughness.

The experience of Dr. Joslin and his associates is spread over forty-eight years, covers about 29,000 diabetic patients (of whom more than 8,000 have died), about 2,200 children and more than 300 pregnancies. During this period major changes in therapy and understanding of the disease have taken place. The average age at death has risen from 44 to 64 years. It is now therefore almost the same as in nondiabetic persons. The careful follow-up records and analyses of their own cases made by the Boston group of clinicians provides an invaluable source of statistical data on many subjects. Largely because of them the estimated million diabetic subjects in this country are now able to obtain life insurance.

The picture of the disease painted in faithful detail in this volume from the point of view of such extensive contact is literally the backbone of modern knowledge, in English speaking countries at least, regarding diabetes mellitus. Every physician who is interested in the disease should have the book available for reference.

Nursing in Commerce and Industry. By Bethel J. McGrath, R.N., Chief Industrial Nursing Consultant, American Association of Industrial Nurses, Minneapolis. For the National Organization for Public Health Nursing. Cloth. Price, $3. Pp. 356, with illustrations. Commonwealth Fund, Division of Publications, 41 E. 57th St., New York 22; Oxford University Press, Amen House, Warwick Sq., London, E. C. 4, 1946.

This book, by the former industrial nursing consultant of the National Organization for Public Health Nursing, is by all odds the most authoritative and readable textbook on industrial nursing which has been published to date. Written by a nurse who has actually worked in commerce and industry and who knows the problems from first hand observation, it answers a need long felt not only by the nursing profession but by employers, personnel workers and others concerned with the development of sound health programs in industry. Dr. Alice Hamilton has written an introduction in which she comments on the great changes which have taken place in industrial medicine since she first entered that scene in 1910. Mrs. McGrath's basic interest in industrial nursing is interwoven with allied fields, and her subject matter covers a wide territory. The book opens with a history of industrial nursing since the first nurse was employed in 1895 to serve the workers of the Vermont Marble Company of Proctor, Vt. Chapters follow on the relationships of the nurse with "top management," personnel and safety departments, employees and employee organizations; physical facilities of an industrial trial health service, healthy working environment; a health program for every worker; occupational accidents and hazards; occupational and nonoccupational diseases; mental hygiene, sight conservation, orthopedic nursing; nutrition; problems peculiar to women; communicable disease control, records and reports; rehabilitation, workmen's compensation; welfare activities, and part time nursing service given to industry by outside organizations. Special attention is devoted to the need for competent medical direction of the nurse in the plant. Whether the physician in charge is full time, part time or on call, the nurse must have a clearcut understanding of the amount and kind of authority he has delegated to her and must have suitable written orders. These topics give some indication of the subject matter the author covers. The book is scholarly, the material well arranged, the format pleasing. There are charts, samples of record forms, samples of standing orders, and in addition to a comprehensive list of references at the end of each chapter also a listing of sources of information. The book fulfils the implications of its title. Dr. Hamilton has concluded her introductory comments with the statement "This book is not only for nurses, it is for the general public." It will repay careful study by those in close contact with workers, and it will prove helpful to any whose primary interest and concern are in humanity.

Ophthalmic Surgery and Sight-Testing. By M. A. Kamath, M.B. & C.M. Second edition. Cloth. Price, 6 rupees. Pp. 297, with 67 illustrations. The Author, Planters Lane, Mangalore, S. K. Dt., 1944.

This is intended for the general practitioner in India for care of patients too far from the centers where trained ophthalmologists are available. The book is very elementary and includes chiefly the diseases encountered in India. The author describes surgical procedures which are often done by practitioners in India. Many general surgeons in mission hospitals in India do 200 operations in a year for cataract. On page 160 when writing of complications of the cataract operation the author states that detachment of the choroid is due to hemorrhage and causes severe pain. He has confused this condition with expulsive hemorrhage of the choroid. Detachment of the choroid is quite common after intraocular operations and disappears without treatment in a few days. The book may be of value to the general practitioner in India but will have no sale in the United States, where many much more authoritative works are available.

Annual Review of Biochemistry. Edited by J. Murray Luck, James H. C. Smith and Hubert S. Loring. Volume XV. Cloth. Price, $5. Pp. 687, with illustrations. Stanford University, California: Annual Reviews, Inc., 1946.

The present volume of the annual reviews of biochemistry maintains the high standards set by its predecessors. Well indexed, it is an exceedingly useful means of locating information recently published in this field, and the mode of treatment has the advantage that each item is critically evaluated and oriented with respect to other items. The twenty-one reviews deal with biologic oxidations and reductions, nonoxidative enzymes, plant carbohydrates, the chemistry of the lipids, the chemistry of the proteins and amino acids, the chemistry of the steroids, carbohydrate metabolism, fat metabolism, the metabolism of proteins and amino acids, the vitamins, the chemistry of the hormones, the biochemistry of teeth, growth factors for micro-organisms, photosynthesis, the respiration of plants, the biochemistry of yeast, bacterial metabolism, immunochemistry, organic insecticides, the viruses and inactivation and detoxication of pressor amines. The excellent quality of this book adds to the significance of the opening tribute on page vii to the memory of Carl L. A. Schmidt.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

PENICILLIN ALLERGY

To the Editor:—A man has had morning attacks of sneezing and rhinitis for several years, which were believed to be due to cigarets. In 1932 he developed a mild urticaria following the use of amidopyrine, which disappeared when the drug was discontinued. Two brothers have asthma and hay fever respectively. Six weeks ago he developed a sinus and bronchial infection and discontinued smoking. The sneezing and rhinitis stopped promptly and have not recurred. For the sinus infection he was given two injections of 50,000 units each of penicillin in oil (Solvecillin) at *twelve hour intervals followed by 20,000 units in isotonic solution of* sodium chloride every three hours for five doses. The sinus infection was cured. However, twelve days after penicillin therapy the patient developed urticaria, which has persisted for four weeks. Pyri-Benzamine (Ciba) 100 mg. three to four times a day controls the itching and the rash, but, if this medication is not taken regularly urticaria breaks out on different areas of the body. Calcium gluconate 15 grains (1 Gm.) four times a day was given for several days. Is the urticaria due to penicillin? Should allergic tests be done? What other treatment is advised?

Warren L. Trexler, M.D., Topton, Pa.

Answer.—Urticarial reactions occurring several days after penicillin administration constitute the most common allergic manifestation from this drug. Such a reaction usually lasts from one or two days to three or four weeks. In some cases the urticaria continues to persist. In such instances two possible explanations can be offered. One possibility is that new additional sensitivities have been added to the penicillin allergy, perhaps because of modification of the sensitizing mechanism. The other explanation of this phenomenon may be that the allergic reaction to penicillin may initiate a conditioning of tissues so that they now respond similarly to other stimuli with release of H-substance responsible for vascular changes resulting in urticaria.

Calcium salts intravenously are more effective than calcium orally. Nonspecific treatment such as typhoid or colon bacillus vaccine subcutaneously may be effective in altering the conditioning mechanism. Skin tests usually fail to give the desired information in the etiologic diagnosis of urticaria. It is better to observe the patient's diet and other exposures to allergenic substances. Is he taking other drugs? If so, these drugs should be avoided. Restricted diets are usually indicated in such cases. One of the simplest diets is a diet composed exclusively of milk products. A less radical diet is one eliminating such foods as fish, nuts, fresh fruits and vegetables.

SENSITIVITY TO GALLBLADDER DYE

To the Editor:—A woman aged 58 had a severe reaction on the evening after taking a gallbladder dye (Priodax), with the sudden development of severe chills, a temperature of 104.4 F. and severe generalized pains specifically localized in the pelvic girdle and requiring ¼ grain (15 mg.) of morphine sulfate for relief. The following day her temperature was normal but she was badly weakened by this febrile episode. On the second day after the episode she felt perfectly well. She had never previously had any similar illness. There was no evidence of chronic malaria, infection or influenza. It was suspected that the reaction was due to the ingestion of the gallbladder dye. Previous administration of iodides by mouth had been attended by unusual amounts of prostration, which had been thought elsewhere to be sensitivity to the iodides. The Graham Cole study has not been repeated. Has any idiosyncrasy of this type been reported?

M.D., Illinois.

Answer.—Since the *introduction of Priodax in roentgenology* of the gallbladder numerous articles have appeared in which the toxic symptoms of the drug have been discussed. The symptoms encountered include nausea and vomiting, diarrhea, mild griping abdominal pain, burning on urination, epigastric distress, burning of the throat, dizziness and headaches. None of these have been severe. Severe reactions of the type described in the inquiry were not encountered in 3,000 gallbladder visualizations in a large clinic in which the drug was used. Similarly, perusal of the current literature does not yield further information on the subject. Although one cannot rule out Priodax as the cause of this reaction without further tests, it is quite possible that the offender may be the iodine radical contained in the drug, since the patient is known to be sensitive to it. Investigation of an idiosyncrasy to both iodine and Priodax may be undertaken, using one of the accepted dermatologic methods.

TREATMENT OF SCABIES

To the Editor:—An entire family consisting of 2 adults and 2 children is under treatment for scabies. The condition has been present for over six months. They have been under the care of competent men and have received numerous courses of sulfur and benzyl benzoate with apparent cures, only to have recurrence in one or two weeks. The treatments were properly applied and followed by correct sterilization of the personal and bed clothing. The family lives in a one story single house. How long can Acarus scabiei live away from the human host (i. e., on sheets or clothing)? Can the scabies mite live in furniture, toys and other household fixtures and for how long? Is it necessary to remove the family temporarily and fumigate the house to rid the house of Acarus scabiei? What method of treating the bedding is best?

Irving Saffran, M.D., Dorchester, Mass.

Answer.—Experiments by Mellanby, Johnson, Bartley and Brown (*Bull. Entomol. Res.* **33:**267, 1942) indicated that at 55 F. and 90 per cent relative humidity the majority of itch mites died within one week when kept off the human host. A few survived as long as fourteen days. At temperatures below 55 F. survival times were shorter. In careful experiments carried out in England on volunteers during the war (Mellanby, Kenneth: *Brit. M. J.* **2:**405 [Sept. 20] 1941) success was attained only twice out of sixty-three trials in transmitting the mite through infested underclothing and blankets even though conditions were made as favorable as possible to successful transmission. On the other hand, even slight personal contact serves as an effective means of spread. Most instances of persistence of the infestation in families are the result of incomplete treatment without the repetition so necessary to complete eradication of second or third generation mites. Although benzyl benzoate is the most potent carcopticide known, it is difficult for the patient to apply the liquid or cream preparations satisfactorily himself. Sarcoptes is sensitive even to moderate heat. Adult females in the experiments noted were killed in ten minutes at 120 F., in thirty minutes at 117.5 F. and in twenty-four hours (not more than forty-eight hours) at 82 F. It would appear from these experiments that one might kill the mites in a house in one week end by maintaining a temperature of 85 to 90 F.

PAINFUL VENOUS DILATATION

To the Editor:—A white woman aged 44 developed generalized acute intermittent pains two years ago along the course of the veins in the arms and legs. During the attacks of pain the particular veins involved become dilated and puffed up and are extremely tender to touch. This occurs in the various parts of the extremities but is most pronounced in both the arms and the shoulders. The patient has tried physical therapy and various types of intravenous injections (including sodium citrate) without relief. The pain is so severe in the morning that she is unable to rise. The past history includes scarlet fever at the age of 31 and an appendectomy at 30. Her menstrual history is normal. *The pulse, blood pressure and temperature are normal. Serologic tests,* sedimentation rate and blood count are normal. The patient has been hospitalized for observation. We are unable to find records of similar cases. Please discuss the diagnosis.

Michael Smith, M.D., West Palm Beach, Fla.

Answer.—The data supplied by the inquiry do not suffice to give constructive help. It is stated that the veins puff up and become tender intermittently, particularly in the arms and shoulders. If the superficial network of veins is meant, they are ordinarily not visible in the shoulders except in the presence of an obstruction of the subclavian veins or of the superior vena cava. It is not clear whether these attacks represent sudden rises in venous pressure, generalized or localized, or whether they are attacks of venospasm or of periphlebitis. The lesion may be neurologic or functional.

TOXIC EFFECTS OF CASITE

To the Editor:—Are there any ill effects from the use of casite by automobile mechanics?

Riley Burnett, M.D., Biloxi, Miss.

Answer.—Casite is a solvent designed for the removal of sludge from motors (not to be confused with "Caseite," an unrelated hardener for metal treatment). The formula for casite may have been modified within the past few years. At one time this fluid had the following characteristics: a distillation range with the initial point at 334 F. and an 85 per cent completion at 700 F.; flash point 180 F.; free from acid; specific gravity 0.916. While identification is incomplete, it is probably a naphtha derivative akin to kerosene and gas oil plus a base of light engine oil. Dermatitis (oil furunculosis or naphtha dermatitis) may follow skin contact. Naphtha vapors from gross exposure may provoke "naphtha jags," an acute condition resembling acute alcoholism. Prolonged excessive exposure may induce a rare condition, "chronic naphtha poisoning," with features resembling multiple sclerosis.

TRANSTHORACIC VAGOTOMY

The Effects in 57 Patients with Peptic Ulcer and the Clinical Limitations

K S GRIMSON, M D
G J BAYLIN, M D
H M TAYLOR, M D
F. H HESSER, M D
and
R W. RUNDLES, M D
Durham, N C

Interest in vagotomy as a surgical treatment for peptic ulcer has been revived during the last four years Reports by Dragstedt and his associates,[1] by our group[2] and by Moore and his associates[3] have dealt primarily with physiologic changes Brief clinical reports have described encouraging therapeutic results. It has been emphasized that distressing complications may occur and that final conclusions are not warranted until more patients are observed for a longer time. Nevertheless, clinical trial is now widespread.

Even though final conclusions are not possible it seems advisable that current observations be reported and that tentative impressions of clinical limitations and of the significance of complications be presented Detailed reports of physiologic, roentgenologic and chemical studies will be abstracted in this report and later presented in detail by individual authors

Fifty-seven patients with refractory or frequently recurring peptic ulcer were treated by transthoracic vagotomy or transthoracic vagotomy and gastroenterostomy from July 1944 through September 1946. Some of the results in 50 of these patients have been presented.[2] Section of the vagus nerves was accomplished through a left thoracotomy wound by resecting the two main trunks and the branches that lie along the lower third of the esophagus[4] Gastroenterostomy when used was performed through a transverse abdominal incision. Table 1 presents the data on the type of operation employed, the location of ulcers and the duration of symptoms One patient had a bilateral transthoracic splanchnicectomy for hypertension at the time of vagotomy for duodenal ulcer. Four were explored through separate abdominal incisions just before vagotomy to verify the presence of ulcer. There was 1 death seventeen days after combined vagotomy and gastroenterostomy due to rupture of the stomach after an acute gastric dilatation and later a terminal massive hemorrhage from a duodenal ulcer

All the patients were studied in the hospital during the week before operative intervention and with 1 exception during the first two weeks afterward Forty-six have been hospitalized for follow-up study at three months and then at yearly intervals Of these, 35 have been readmitted between three months and one year, 3 between one and one and one-half years and 8 between one and one-half to two and one-half years after operation[5] The current status of each patient has been ascertained during office visits and by questionnaire

During each study period in the hospital gastric secretions were obtained by overnight suctions, frequently before and after the administration of histamine, and occasionally before and after insulin hypoglycemia and caffeine test meals. Gastric motility was studied by the intragastric balloon method and by fluoroscopic examination after the ingestion of barium. Repeated roentgenologic examinations of the small and large intestines were made The effect of stimulation of the vagus nerves during high spinal anesthesia has been determined in 4 patients The effects of various parasympathomimetic drugs were also investigated

GENERAL CLINICAL RESULTS OF VAGOTOMY

The effects on major symptoms of ulcer are abstracted in table 2 *A* and will be amplified briefly. Before vagotomy each of the 56 patients had experienced some pain; 35, tarry stools or hematemesis, and 43, vomiting The number with severe pain, frequently recurring episodes of massive hemorrhage and frequent vomiting is given in table 2 *A*. After vagotomy severe pain or massive hemorrhage did not recur. Periodic mild or atypical ulcer-like pain was described

[4] We prefer the terms vagotomy and vagus section to "vagus resection" and "vagectomy," since the physiologic effect is produced by division of the nerves and partial excision is added only to minimize regeneration

[5] We are indebted to the members of the surgical resident staff for routine work that has made this study possible and to Drs J M Ruffin and R C Smith, who have worked with our group as medical consultants

during the early months after operative intervention by 2 patients and later by another 2 patients, but only after heavy drinking. One patient who described recurring mild ulcer-like pain for thirteen months and occasional black stools had a persistent duodenal ulcer. A single episode of hematemesis occurred in 2 patients, seventeen and thirty-seven days after vagotomy. There has been no other recurrence of bleeding. Frequent vomiting continued in 1 patient with an adequate gastroenterostomy Seven patients described occasional vomiting during the first several months.

TABLE 1—*Type of Operation Employed in Fifty-Seven Patients, Location of Ulcers and Duration of Symptoms*

	Number of Patients in Each Group	Average Duration of Symptoms, Yrs.
A Transthoracic vagotomy alone		
Duodenal ulcer *	32	10
Marginal ulcer after gastroenterostomy	3	8
Marginal ulcer after subtotal resection	6	14
Gastric ulcer	4	6
B Transthoracic vagotomy and gastroenterostomy		
Gastroenterostomy necessary after vagotomy (4 duodenal ulcers, 1 stoma, 1 gastric)	6	8
Gastroenterostomy performed at time of vagotomy (4 duodenal ulcers, 1 gastric)	5	16
Gastroenterostomy performed before vagotomy (1 duodenal ulcer and 1 prepyloric gastric)	2	25

* One patient with a duodenal ulcer present thirteen months after vagotomy was treated by subtotal gastric resection

Changes of body weight are summarized in table 2 *B*. The average reduction of weight from the maximum before or during the period of difficulty with ulcer preceding vagotomy was 24 pounds (11 Kg.). Of the 50 patients who gained weight after vagotomy, 21 regained their maximum weight. Six patients have lost weight. Four of these at four to six months have an average loss of 20 pounds (9 Kg.). The remaining 2 at eight and twenty-seven months have lost 8 and 6 pounds (3.6 and 2.7 Kg.).

Disability as judged by the patient is abstracted in table 2 *C*. After vagotomy 38 patients are able to work full time. Fifteen can work but half time. Of these each complained of weakness, 7 of pain in the incision and in the chest, 6 of nervousness and 1 of severe diarrhea. Of the 3 patients unable to work after vagotomy, 2 are incapacitated by weakness The third, a veteran totally disabled for thirty years, continues to complain of pain, weakness and nervousness

Statements concerning satisfaction with the results of surgical intervention are presented in table 2 *D*. Forty-eight patients are completely or moderately well satisfied because of relief of pain and ability to eat a less restricted diet. The only seriously dissatisfied patient is disabled by vomiting and aggravation of a chronic diarrhea which was present before the operation. Although he has been relieved of symptoms of ulcer for twenty-one months, hospitalization has been necessary on three occasions because of diarrhea and loss of weight.

COMPLAINTS AFTER VAGOTOMY

After vagotomy most patients have described new symptoms, which probably result from the removal of parasympathetic innervation of the upper part of the gastrointestinal tract (table 3). These symptoms did not ordinarily cause serious dissatisfaction. In a few cases, however, they were serious.

Forty patients experienced uncomfortable fulness of the stomach (table 3 *A*). Usually this occurred with or after meals. Occasionally during the early period after vagotomy it was persistent. Foul eructations (table 3 *B*) usually occurred infrequently and without reference to meals. They were described as a sour belch or as having a sulfurous odor like that of rotten eggs.

Of the 28 patients who described swelling or distention of the abdomen (table 2 *C*), 15 noticed difficulty only after eating or overeating. The remaining 13 described no relationship to meals and attributed distention to "gas." Colicky abdominal pain, usually described as mild "bowel cramps" or "gas pains," occurred in 38 patients (table 3 *D*). Seventeen noticed these pains only after eating.

Intolerance of food (table 3 *E*) has occurred infrequently. After undergoing vagotomy patients have been advised that they may eat an unrestricted diet but are to avoid overeating and that when gastric retention has developed they are to use a low residue diet. The majority have resumed an unrestricted diet without ill effect. Only 12 patients described intolerance to foods, such as coffee, onions, beans or watermelon. This intolerance continued in 7.

Temporary difficulty during swallowing was noted by 21 patients (table 3 *F*). The symptoms suggested that food had lodged in the lower part of the esophagus. One patient had such difficulty before the vagotomy was performed; it became less troublesome afterward.

TABLE 2—*General Clinical Results of Treatment in Fifty-Six Patients*

Only partially satisfied	56	7
Dissatisfied		1

In the remainder of patients the trouble developed after the operation. One patient experienced it for five days during the period of hospitalization immediately after operative intervention. Two described it as occurring once or twice two or three weeks after operation and lasting a minute or two. One was readmitted two weeks after vagotomy with complete obstruction which had been present four days. There was decided narrowing of the lumen of the esophagus extending the full length of the operative site. This subsided spontaneously after several days. There was no residual constriction by fluoroscopy. Eleven described minor difficulty with swallowing as occurring soon after the operation and lasting several weeks; 3 described it as lasting several months, and 3 as continuing at four, five and seven months, although with decreasing frequency and severity. Roentgenologic examination of the esophagus of each of these patients at three months and later did not reveal evidence of obstruction or achalasia.

Table 3.—*Complaints of Patients After Transthoracic Vagotomy (Fifty-Six Patients)*

	Difficulty During 1st 3 Mos., No of Patients	Persisting Difficulty, No. of Patients
A. "Fulness" of the stomach	40	16
B. Eructation with a "rotten egg" taste or odor	26	15
C. Swollen abdomen	28	14
D. Collcky abdominal pain		
Frequent or daily	13	10
Occasional or periodic	25	12
E. Intolerance of certain foods	12	7
F. Transient obstruction of lower esophagus	21	0
G. Episodes of acute abdominal pain	..	6

Episodes of acute abdominal pain (table 3 *G*) occurred after vagotomy in 6 patients and necessitated their admission to the hospital. Although the onset and course varied from patient to patient, certain symptoms and observations were similar. The pain was intense and colicky; nausea or vomiting developed; food or alkali gave no relief, and the abdomen was moderately distended. Roentgenologic examination revealed gas in the stomach or colon. Sounds of intestinal movement were exaggerated and borborygmus usually occurred. Leukocytosis or elevation of temperature did not occur. In 4 patients symptoms were so severe that an exploratory laparotomy was considered. In no instance was the cause of the pain adequately explained.

The onset and duration of the pain varied. One patient had recurring attacks during the third month after operation, each followed by diarrhea. A second experienced severe pain in the lower part of the abdomen and back ten months after operation. Both recovered spontaneously and have not had recurrence. The third patient experienced severe colicky pain in the lower part of the abdomen eighteen months after vagotomy. The symptoms subsided within forty-eight hours. A fourth returned twenty-eight months after vagotomy with lower abdominal pain which had persisted for six weeks and which he stated was not like his previous ulcer pain. This patient is of interest since he had a nonfunctioning gastroenterostomy stoma at the time of operation and three months later. After thirteen months fluoroscopy revealed a poorly functioning stoma with star-shaped mucosal folds resembling a healing ulcer of the stoma. At the time of the attack of abdominal pain thirteen months later, the function of the stoma had improved and there was less evidence of a mucosal defect.

The fifth patient returned repeatedly with episodes of acute abdominal pain. After four months an incarcerated Meckel's diverticulum was removed and a pyloroplasty was performed to relieve retention distal to a high gastroenterostomy. Symptoms continued, and twelve months later a laparotomy was performed and adhesions about an old gastrocolic fistula were divided. Symptoms recurred until twenty months after the vagotomy and then subsided. There was no evidence of recurrent ulcer by operative or by roentgenologic examination.

The sixth patient began having episodes of colicky abdominal pain two months after vagotomy, and they recurred at frequent intervals during the next eleven months. Occasional tarry stools were described, but there was no anemia. The last attack was the most severe and brought the patient to the hospital as a subject for emergency treatment. There was severe colicky upper abdominal pain, greatest on the left and also constant deep epigastric pain. The abdomen was moderately distended. The distention and colicky pain subsided spontaneously within three days, but the deep epigastric pain persisted. A fluoroscopic examination revealed a duodenal ulcer crater, and a subtotal gastric resection was performed.

It is of interest that 31 of 56 patients treated by vagotomy describe the passage of excessive amounts of gas through the rectum. This was more evident during the early months and later gradually subsided.

Patients have complained of general symptoms in addition to those presented in table 3. These did not seem to be related to alterations of gastrointestinal function.

Many patients complained of weakness before operative intervention was performed. Afterward, weakness was described during the first three months by 36 patients. It subsided in all but 9 during convalescence. Of these 9, 2 have diarrhea, 1 gastric retention necessitating a soft diet, 3 retention with frequent foul eructations and 3 abdominal distention and gas.

Nervousness has been listed as a major cause of disability by 13 patients and has persisted in all but 1. It is of interest that 2 have volunteered the statement that gas or distention makes them nervous.

Table 4.—*Change of Bowel Habit of Fifty-Six Patients with Vagotomy*

	Before Vagotomy, No. of Patients	After Vagotomy, No. of Patients
A. Persistent change		
Normal bowel habit	11	33
Constipation		
Continuous or recurrent at frequent intervals	37	1
Recurrent at occasional intervals	0	5
Diarrhea (severe)		
Continuous or recurrent at frequent intervals	1	4
Diarrhea (mild)		
Recurrent at occasional intervals	2	5
Tendency to soft or moderately frequent stools	0	8
Constipation and diarrhea		
Constipated but having occasional periods of diarrhea	5	0
B. Temporary change		
Diarrhea; severe, temporary	0	20

Each patient has had pain in the incision and the left side of the chest resembling that which occurs after any thoracotomy. Pain occurred immediately after operation, became more intense during the first week or two and then gradually subsided. Six patients described persisting discomfort and 2, numbness.

CHANGE OF BOWEL HABIT

Vagotomy usually effected a change of bowel habit. Patients were often constipated before operation. Their first stools afterward were usually normal or soft and frequent. The bowel habits before operation and four to thirty-one months afterward are compared in table 4 *A*. Eleven of the 56 patients had ordinary bowel habits before operation. Afterward 33 had normal habits. Thirty-seven had persistent difficulty with constipation before vagotomy. After operation constipation occurred infrequently.

In 4 patients a chronic diarrhea developed, with five to twelve stools a day. One patient with exacerbation of a preexisting gastrointestinal disturbance and with an adequately functioning gastroenterostomy has had diarrhea for twenty months. Another with an adequately functioning stoma after subtotal gastric resection was constipated before vagotomy and since then has had diarrhea for ten months. The remaining 2 had normal bowel movements before operative intervention. One had a gastroenterostomy one month before vagotomy and has diarrhea, persisting at six months. The fourth patient did not have a gastroenterostomy but has had decided symptoms of gastric retention with food intolerance and recurrent diarrhea persisting twelve months.

Table 5.—*Changes of Acidity of Fasting Gastric Contents*

Free ac	1	0	0	.

Five patients have mild persistent or recurrent diarrhea with as many as three or four movements a day. Eight have soft stools once or twice a day. Some patients with diarrhea state that the stools are lighter than normal in color.

In addition to the persistent change of bowel habit just described (table 4 *A*) a temporary period of diarrhea with as many as six to fourteen stools a day occurred in 20 patients (table 4 *B*). In 3 it appeared within ten days of the operation and in 16 during the first weeks of convalescence. Diarrhea usually lasted several days to a week. Most patients had a single episode, but a few had several. This temporary diarrhea occurred during the first month in 11 patients. There were recurrences during the second month in 5, during the third month in 2 and for six months in 1. Subsequently 15 of the 20 patients with temporary diarrhea had normal bowel habits and 5 had a tendency to soft or moderately frequent stools.

During the periods of hospitalization before and after vagotomy special studies have been performed by the co-authors of this paper or under their direction. Ideas for study or for interpretation of results have come from individuals or have originated in group discussions. Each study will, therefore, be abstracted under the names of the co-authors, who will later publish detailed reports.

STUDIES OF GASTRIC SECRETIONS (H. M. TAYLOR)

Secretions of the fasting stomach and secretions aspirated before and after stimulation by histamine, insulin hypoglycemia or caffeine were usually readily obtained and analyzed before vagotomy. After operation suction tubes occasionally became blocked by particles of food present in the stomach long after meals. Lavage of the vagotomized stomach is often difficult because of retained gastric content, and some samples of gastric secretions were contaminated by particles of food. Frequently bile was present in samples obtained after the operation. With due allowance for these difficulties the following results seem reasonably reliable.

The volume and acidity of secretions obtained during a continuous twelve hour overnight aspiration were determined before and after vagotomy in 54 patients. The average volume of gastric fluid of the group of 32 patients with duodenal ulcer and vagotomy alone was reduced from 888 cc. before operation to 340 cc. immediately afterward. The average of 17 patients tested between three months and one year was 226 cc. The average of 6 tested between one and two and one-half years was 346 cc. Reduction of volume also occurred in the patients with gastroenterostomy, subtotal resection or gastric ulcer.

Changes of acidity are presented in table 5. For convenience the numbers of patients having no free acid, less than, or more than 30 clinicial units are presented rather than individual acidity values. The individual values used to construct this table were obtained by analyses of samples from overnight suctions and fasting samples obtained before routine tests. Occasionally unexplained variations occurred in consecutive fasting samples. These are not included in the grouping presented in table 5. It is evident that the number of patients with no free hydrochloric acid or less than 30 clinical units increases after vagotomy and that among the 10 patients tested after one to two and one-half years only 1 has more than 30 units.

Responses to histamine, caffeine and insulin have varied. Before vagotomy histamine usually produced a pronounced elevation of free hydrochloric acid in gastric secretions. Afterward there was little or no response to histamine in half of the patients. Insulin hypoglycemia or caffeine usually produced a great increase in free acid before vagotomy. Afterward the response was variable; most patients had no increase of free acid, some a moderate increase and few a decided increase. We do not know why these variations occurred and have not yet repeated these tests under experimental conditions that permit evaluation of the possible roles of obstruction, retention or rapid emptying of the stomach.

In general values for combined acid in fasting specimens are higher after vagotomy than they were before operation.

Serial determinations of free hydrochloric acid and hydrogen ion concentration, made during operation on 4 patients, revealed a prompt cessation of secretion of free acid after division of the nerves.

STUDIES OF GASTRIC MOTILITY (HESSER AND BAYLIN)

Intragastric Balloon Studies

Fluctuations of total intragastric pressure were measured by introducing a rubber balloon into the stomach, connecting it to a recording bromoform manometer and inflating it at two or three minute intervals with successive 50 cc. increments of air to a volume of 300 cc. Recordings were continued forty-five minutes to three hours. This technic differs from that used by others,[6] who employed balloons inflated only to 50 cc. and recording tambours. The results have also differed. We have not controlled by use of the fluoroscope the position of the balloons in the stomach or the amount of retention which may have been present in some patients even though they had been fasting twelve hours before each test. Our results have, nevertheless, been consistent.

Thirty patients were tested before vagotomy, 42 immediately afterward, 34 between three months and one year and 11 between one and two and one-half years. For convenience intragastric pressures recorded by the bromoform manometer have been converted into equivalent values of water and will be presented as centimeters of water. The pressures necessary to inflate the balloons to a volume of 300 cc. before and after they were placed in the stomach varied from 4.0 to 5.8 cm. Additional pressure on the balloon when placed in the stomach is defined as total intragastric pressure. The level of pressure observed during intervals between contractions is defined as resting pressure. This pressure is caused by partial contraction of the smooth muscle of the gastric wall on the stomach content. Fluctuations of total intragastric pressure above or below this level are defined as waves of gastric contraction. For convenience, values will be presented as the average of pressures of all patients tested during each time period before and at intervals after vagotomy.

The average resting pressure of the patients who had vagotomy alone for duodenal ulcer was 4.0 cm. before vagotomy and increased to 8.2 cm. during the first two weeks afterward. At three months to one year the average increased to 8.5 cm. and at one to two and a half years to 10.5 cm. Conversely, the amplitude of gastric contraction waves decreased but waves became more frequent and rhythmic with a persistent pattern. The average height above the resting pressure of waves of gastric contractions in this group of patients was 20.5 cm. before vagotomy and 1.6 cm. immediately afterward. At three months to one year, and also at one to two and a half years, the average was 2.8 cm. Similar increases of resting pressure and persistent decreases in the amplitude of contractions occurred in patients with gastroenterostomy and with gastric ulcer. There was an occasional exception, particularly in the subtotal resection group in which rhythmic contractions before vagotomy were low.

Before vagotomy sudden stretch produced by introduction of 50 cc. of air into the balloons produced a contraction, or stretch reflex, evidenced by an increase of intragastric pressure lasting five to fifteen seconds. This did not occur after vagotomy. Also, prolonged three or four minute increases of intragastric pressure, or so-called tonus contractions, occurred in 2 patients before operation and were seen in 3 afterward.

Roentgenologic Examination After the Ingestion of Barium

Vagotomy has effected remarkable changes of peristalsis, the amount of retention six hours after the ingestion of barium and the size of the stomach. These changes have been observed during fluoroscopic examination and recorded by films. Studies made on 56 patients before and at intervals after operation are presented in table 6. For convenience, peristalsis has been described as active or sluggish, retention as greater or less than 30 per cent at six hours and the size of the stomach as within normal range or enlarged.

TABLE 6.—*Changes of Peristaltic Activity, Retention and Size of Stomach (Roentgenologic Examination After Barium Meal)*

		After Vagotomy

Enlarged	0	3	2	..

Before operative intervention peristalsis was active in the 32 patients with duodenal ulcer subsequently treated by vagotomy alone (table 6 *A*), variable in patients with stoma or gastric ulcer or with obstruction later treated by gastroenterostomy (table 6 *B* and *D*) and sluggish or absent in those with stoma ulcer after subtotal resection (table 6 *C*). In most of the patients after section of the vagus nerves peristalsis was sluggish or apparently absent. Peristalsis persisted actively but apparently abnormally in a few. Deep, forceful antral contractions were seldom seen. Variations of activity were often observed in consecutive examinations of the same patient.

---

[6] (*a*) Starr, I., and Ferguson, L. K.: Beta Methylcholine Urethane: Its Action in Various Normal and Abnormal Conditions, Especially Post Operative Urinary Retention, Am. J. M. Sc. **200**: 372-385, 1940. (*b*) Moore, Chapman, Schulz and Jones.[3]

Before the operation, the retention of barium at six hours occurred in only 6 of the 32 patients with duodenal ulcer (table 6 *A*) who did not have subsequent gastroenterostomy. These 6 had retention varying from 5 to 30 per cent. Retention was not present preoperatively in the patients who had resection or who had gastric ulcer. It was usually present preoperatively only in those patients (table 6 *B*) subsequently treated by both vagotomy and gastroenterostomy. After operation, with few exceptions, there was a remarkable increase in the amount of barium retained at six hours. Twenty-three of the 36 patients with duodenal or gastric ulcers treated by vagotomy alone had 50 to 100 per cent retention at six hours, and many had retention at twenty-four hours. Complete retention in another 5 patients necessitated the secondary gastroenterostomy that placed them in group *B*, table 4.

Prior to operation moderate enlargement of the stomach was present in only 2 of the 32 patients with duodenal ulcer who did not have subsequent gastroenterostomy (table 6 *A*). Enlargement occurred preoperatively in 9 of the patients (table 6 *B*) who subsequently had gastroenterostomy at the time of or after vagotomy. Enlargement of the stomach was not present before vagotomy in the resection or gastric ulcer groups. After section of the vagus nerves enlargement of the stomach frequently occurred. Enlargement varied from twice the normal or preoperative size to three or four times normal. Three patients returned with acute dilatation of enormous size. Retention was most frequent and persistent in patients with duodenal ulcer treated by vagotomy alone, but it also occurred in some patients with gastroenterostomy or gastric ulcer.

It is of interest that significant change of peristalsis, retention or size of the stomach did not occur in 4 of the 5 patients with stoma ulcers that developed after subtotal gastric resection.

STUDIES OF SMALL INTESTINE AND COLON (RUNDLES AND BAYLIN)

Roentgenologic examinations of the small intestine were performed in 26 patients, of whom 12 were studied before as well as after vagotomy. Delay of emptying of the stomach after operation often made visualization of the small intestine difficult. In general after vagotomy transit through the jejunum was delayed, the caliber tended to increase slightly and the mucosal pattern tended to become coarser. No constant abnormality in the ileum followed the operation. The colon as visualized twenty-four hours after the ingestion of barium or by barium enema showed no definite abnormality.

NEUROLOGIC STUDIES OF ULCER PAIN (F. H. HESSER)

Each patient has been relieved of ulcer pain immediately after operative intervention and before healing could occur. This suggests the possibility of interference with pain pathways mediated by the vagus. To examine this possibility the vagus nerves below the diaphragm were stimulated by crushing in two patients under spinal anesthesia. Pain did not develop. In 2 others also under spinal anesthesia the nerves were exposed in the lower thorax and stimulated electrically and by crushing. These patients complained of pain referred to the neck and not to the abdomen. Stimulation of the intact left vagus in the neck of 1 patient under local anesthesia produced pain referred to the neck and also "heart burn" and "sour stomach." It is a common observation that spinal anesthesia high enough to block splanchnic pathways relieves pain caused by penetrating ulcer. Major visceral pain pathways, therefore, course through the splanchnic nerves and are intact after vagotomy.

Of the 56 patients, 4 had no free hydrochloric acid and 7 had little free acid before operation. Since they were relieved of pain afterward, the reduction of acidity which usually occurs after vagotomy cannot be a sole explanation for their relief from pain.

It is of interest that in 1 patient treated during the last three months a duodenal ulcer healed but a gastric ulcer developed. The crater was found incidentally during routine fluoroscopic examination. This ulcer did not produce pain and healed spontaneously.

EFFECT OF PARASYMPATHOMIMETIC DRUGS

Several parasympathomimetic drugs have been studied. Mecholyl chloride (acetyl-beta-methylcholine), Doryl (carbaminoylcholine chloride) and Urecholine (carbaminoyl-beta-methylcholine chloride) have each activated gastric motility after vagotomy as judged by fluoroscopic examination, and neostigmine methylsulfate has occasionally produced moderate activity. Studies using 300 cc. intragastric balloons reveal little or no restoration of activity after Mecholyl, moderate restoration after Doryl, good restoration after Urecholine and no restoration with neostigmine methylsulfate. The clinical use of Urecholine[7] was first studied extensively by Starr and Ferguson.[6a] Its action in vagotomized patients has been described by Machella, Hodges and Lorber,[8] who encouraged our experiments.

The administration of 5 mg. of this drug hypodermically produced a feeling of warmth and later perspiration. Fluctuations of intragastric pressure decreased or absent after vagotomy as recorded by balloons are increased or partially restored by the hypodermic injection of a 5 mg. dose and also usually by the oral administration of 20 or 30 mg.[9] Gastric peristalsis observed during fluoroscopic study is increased by effective doses of the drug hypodermically and also in most cases orally. Urecholine (30 mg. orally) was given to 8 vagotomized patients in whom gastric retention at six hours varied from 50 to 85 per cent. Retention decreased to less than 10 per cent in 6 patients and was unchanged in 2. In these 2 subjects the subsequent injection of 5 mg. of the drug hypodermically produced prompt emptying of the stomach. Transit of barium through the small intestine, usually delayed after vagotomy, was accelerated by effective doses of the drug given by injection or orally. The caliber and pattern of the jejunum reverted to normal.

---

[7] This drug was furnished by Merck & Co., Inc.

[8] Machella, T. E.; Hodges, H. H., and Lorber, S. H.: The Restoration of Gastric Motility by Urethane of B-Methyl Choline After Section of the Vagus Nerves for Peptic Ulcer, Gastroenterology 8: 36-51, 1947.

[9] Some of these experiments have been performed by Dr. R. W. Postlethwait.

Injection of 5 mg. of Urecholine occasionally slightly increased the free hydrochloric acid in gastric secretions of 5 normal and of 5 vagotomized patients.

Urecholine 5 mg. given hypodermically to 4 patients with peptic ulcer accentuated pain on 1 occasion. This result could not be repeated after several days and did not occur in the other 3 patients, even though forceful gastric peristalsis developed. Ulcer-like pain was not produced after vagotomy by single injections of the drug.

Hypodermic injection of 5 mg. of Urecholine or oral administration of 10 mg. three times a day has been employed during the immediate postoperative period in 7 patients. Symptoms of retention or distention otherwise frequently observed were less evident.

Ten milligrams of the drug was given orally three times a day as a symptomatic treatment to 12 patients with complications present one month to two years after operative intervention. In 4 there was apparently no effect and treatment was discontinued. Eight reported relief from abdominal "gas pains" or "rumbling." Four with diarrhea noted decrease in the frequency of movements or a tendency toward constipation. They also noticed that their stools became darker and more normal in color and consistency. Only 5 of the 8 patients who noticed an effect from the drug are now taking it regularly. Of the 3 who stopped, 2 had had temporary recurrence of ulcer-like pain and 1, nausea after the morning dose. Symptoms of warmth and sweating are not evident after the oral administration of 10 mg. of the drug three times a day.

COMMENT

With 1 exception transthoracic vagotomy has evidently effected healing or quiescence of duodenal, marginal or gastric ulcers in 56 patients during a period of observation of four to thirty-one months. This is best evidenced by lasting relief from the pain, hemorrhage or vomiting which was present before operative intervention. Patients have usually gained weight and returned to work. With 8 exceptions they are satisfied.

Transthoracic vagotomy has, nevertheless, several disadvantages. The transthoracic approach does not permit visualization of abdominal viscera. It must be supplemented by exploratory laparotomy unless diagnosis of ulcer is certain and malignancy improbable.

Another disadvantage is the occurrence of obstruction at the outlet of the stomach with retention of gastric content and dilatation of the stomach. Distention, accumulation of fluid and gas and loss of normal peristaltic pattern make these stomachs appear atonic during fluoroscopic examination. Resting intragastric pressure as judged by balloon studies, however, is increased after vagotomy and tonus contractions have occurred. The increase of intragastric pressure may be considered as representing an increase of the partial contraction of smooth muscle of the stomach wall or of the "tone" providing other factors that might increase pressure are controlled. Such factors could be changes of intra-abdominal pressure effected by tone of abdominal muscles or distention of adjacent viscera or, in some patients, the hydrostatic effects of retained gastric content.

Gastroenterostomy relieves retention. It therefore seems probable that decrease or alteration of peristaltic activity together with obstruction at the outlet of the stomach are the important causes of retention and dilatation. In 6 patients in this series secondary gastroenterostomies have been required because of obstruction.

Obstruction may be caused by scar tissue or by inflammation. Often after vagotomy it is a result of malfunction of the physiologic sphincter at the outlet of the stomach. As revealed by fluoroscopic examination the contraction, or tone, of the sphincter may be abnormal after vagotomy. Also forceful peristaltic waves normally propel food to the sphincter and stimulate relaxation and opening. This ejection cycle is not initiated by the feeble or abnormal peristaltic waves which are present after a vagotomy has been performed. Such a physiologic obstruction necessitated a secondary gastroenterostomy in 1 patient with a gastric ulcer. It has also produced retention in 4 patients treated by vagotomy for conditions other than ulcer. One of these required secondary gastroenterostomy. This type of obstruction resembles that observed in animals. It can be relieved by restoring propulsive peristaltic activity with Urecholine. Fortunately the degree of obstruction varies from patient to patient and often does not cause serious difficulty.

Since obstruction and retention may be relieved by adequate gastroenterostomy, Dragstedt now uses this operation at the time of subdiaphragmatic vagotomy for the majority of his patients. In our series in 1 of 7 patients with duodenal or gastric ulcer there developed obstruction which required the performance of a secondary operation. This number may be decreased by use of parasympathomimetic drugs.

Another disadvantage of vagotomy is the occasional occurrence of diarrhea. Most patients are gratified by relief from constipation and the occurrence of normal or soft bowel movements. Temporary severe diarrhea occurred in 20 patients but subsided promptly. A few of these patients obtained relief by vomiting or after lavage and aspiration of foul retained gastric content. Only 4 patients in this series have had persistent, severe diarrhea. Three of these have adequate gastroenterostomies, and their bowel habit has improved after Urecholine has been administered to them orally.

In 6 patients there developed serious episodes of severe, colicky abdominal pain. Detailed examination did not reveal an adequate explanation of the colicky pain. One of these patients had a persistent duodenal ulcer and was treated by subtotal gastric resection thirteen months after vagotomy.

In most patients symptoms related to altered function of the gastrointestinal tract have not been serious. Malnutrition or specific deficiencies have been observed only in 1 patient with a preexisting diarrhea. Parasympathomimetic drugs, such as Urecholine, are being investigated as a treatment of gastric retention, diarrhea and gas pains. Although early results are encouraging, the ultimate utility of these drugs has not been determined.

It is of interest that temporary difficulty in swallowing occurred soon after vagotomy in 20 patients. It was caused in some by temporary narrowing of the esophagus at the operative site and possibly in others by retention of gas or food in the stomach. Achalasia has not occurred as judged by negative roentgenologic examinations and by failure of persistence of symptoms.

A single explanation for healing of ulcer or relief from pain has not been found. Many changes have occurred that might favor healing. Most patients have reduction of acidity or achlorhydria. Also retention of gastric content may favor neutralization of digestive juices. Regurgitation of duodenal juices or bile is frequent after vagotomy. Values for combined hydrochloric acid have increased. Reduction or alteration of gastric peristaltic activity as judged by fluoroscopic examination has occurred after vagotomy. Reduction of amplitude of gastric contractions as judged by balloon study has been more consistent than has reduction of acidity. Nevertheless, ulcers were present without demonstrable peristaltic activity or free hydrochloric acid in some of the patients with gastric ulcer or with stoma ulcer after subtotal gastric resection. In these patients ulcers healed after vagotomy without demonstrable change of motor or secretory activity. Clinical studies of changes of circulation at the site of the ulcer have not been possible. It seems evident by fluoroscopic examination that forceful thrust of gastric content into the area of the ulcer seldom if ever occurs after a vagotomy has been performed. Healing of the ulcer and relief of pain are probably caused by a combination of beneficial changes.

Although transthoracic vagotomy effects healing or quiescence of peptic ulcer, complications occur that limit its clinical application. Until the cause and treatment of these complications are more thoroughly investigated and until results are observed through a longer period of time, final conclusions are not warranted. The following conclusions are, therefore, tentative.

CONCLUSIONS

1. Healing or quiescence of duodenal or gastric ulcers has followed transthoracic vagotomy alone. Nevertheless, disturbances of gastrointestinal function, including gastric obstruction and retention, have occurred frequently and occasionally have produced serious complications. It seems probable, therefore, that vagotomy alone should not be used as a standard treatment for all duodenal or gastric ulcers resistant to medical management.

2. Healing or quiescence of stoma ulcer occurring in 6 patients after subtotal gastric resection has followed transthoracic vagotomy. Since complications caused by retention are less serious in these patients and since conventional surgical treatment has failed, vagotomy may be indicated as a standard treatment.

3. Transthoracic vagotomy combined with some form of gastroenterostomy has been followed by healing of ulcer in 12 patients in whom stoma ulcer has not as yet developed. The incidence of symptoms of retention in this group is low.

4. Alterations of the motor and secretory functions of the stomach have usually persisted as judged by examinations made in 11 patients one to two and one-half years after vagotomy.

AEROSOL PENICILLIN

Blood Levels of Penicillin Obtained by Inhalation of Aerosols Produced by a Combined Steam Generator and Aerosolizer, with the Use of Propylene Glycol, Tents and a Breathing Box

New York

Medicated aerosols afford a new and promising approach to the treatment of bronchopulmonary diseases.[1] Penicillin,[2] sulfonamide compounds,[3] "promin" (sodium p,p'-diaminodiphenylsulfone-N,N'-didextrose sulfonate)[4] and streptomycin[5] have been employed in this manner. Nebulization of the material with oxygen has been the method of application used by the majority of workers.

In recent communications[6] a combined steam generator and aerosolizer has been described, which is simple, effective, inexpensive and readily applicable for home and office use. Preliminary studies with this aerosolizer disclosed that satisfactory aerosols were readily obtained from solutions of theophylline ethylenediamine, epinephrine, sulfadiazine and penicillin—singly or in combinations.[7] Results of the present study have shown that the inhalation of aerosols of penicillin produces a concentration of the drug sufficient to make it effective for treatment not only of bronchopulmonary disease but also of infections in other systems of organs in which use of this antibiotic is indicated.

This work has been aided by a grant from Mr. Martin Goodman, New York.

MATERIALS AND METHODS

Hospitalized patients without known disease of the respiratory tract (except for 1 patient with asthma) served as subjects for the experiments. The calcium salt of penicillin[8] was dissolved in water or in propylene glycol before aerosolization. The blood levels for penicillin were determined in the earlier tests by the micromethod of Fleming.[9] Subsequently, they were estimated by the macromethod devised by Randall, Price and Welch.[10] The results obtained by the use of both these methods are recorded in this paper. Time intervals, as recorded, start with the beginning of inhalation. Control samples of blood prior to treatment with penicillin were analyzed in most cases for antibiotic activity, in order to evaluate properly the results obtained.[11] None of these control specimens displayed any inhibitory action on the growth and multiplication of the test organism.

The aerosolizer[12] used in these studies (fig. 1) has been described in detail elsewhere.[6] In operation, steam escapes from an electrically heated container through a fine aperture in the nozzle. As it passes over a tube which connects the nozzle with the medicament, the steam sucks up and nebulizes the medicament. Penicillin is unaltered by this brief contact with the steam.[6a] The medicated steam expands on emerging from the spout and is, therefore, cool and harmless for inhalation.[13] A screw valve regulates the onset and rate of flow of the medicament. Safety devices include an escape valve for excess steam and an automatic cutoff of current when all the water has been utilized.

The methods of confining and utilizing the aerosol are described in connection with the results obtained.

RESULTS OBTAINED BY VARIOUS METHODS OF INHALATION OF AEROSOLS OF PENICILLIN

1. *Method of Open Inhalation.*—In the application of the open inhalation method, the patient sat about 6 to 8 inches (15 to 20 cm.) away from the aerosolizer to inhale the aerosol, as it was produced, for approximately fifteen minutes per treatment (fig. 2). The steam was cool and harmless at this distance. There was a great loss of penicillin from dissipation (the rate of production of aerosol was greater than the rate of inhalation) and from condensation on the patient's face. Nevertheless, penicillin in measurable quantities reached the systemic circulation.

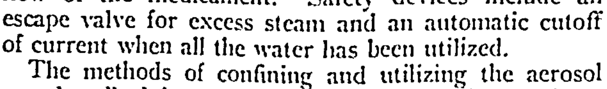

Fig. 1.—A combined steam generator and aerosolizer for the production of medicated aerosols.

Although extremely wasteful, this method has the advantage of simplicity. Self administration is practical and is readily learned by the patient. The penicillin is dissolved in 20 cc. of water or isotonic solution of sodium chloride.

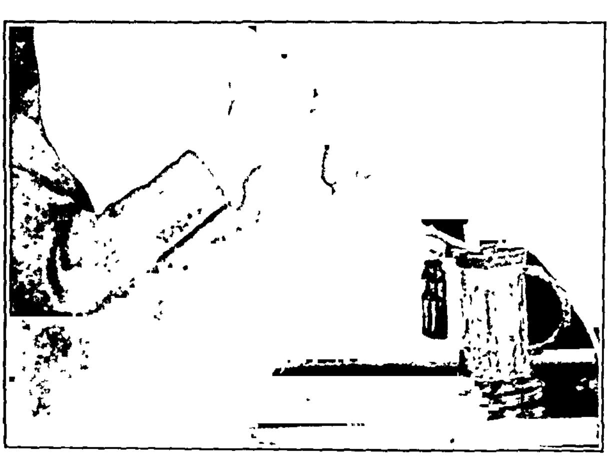

Fig. 2.—Open inhalation of aerosol of aqueous penicillin.

Comment: Subsequent to the aerosolization of 100,000 units, an effective level of penicillin in the blood can be maintained for one and a half hours.

2. *The Air-Tight Chamber.*—In this method, the patient was confined to a chamber 6 by 6 by 7 feet (183 by 183 by 213 cm.), in which 180,000 units of penicillin in 20 cc. of propylene glycol were aerosolized. A blood level of 1.0 unit was obtained in the first half hour (Fleming's method) and none thereafter, although the patient remained in the chamber for over two hours. It is of clinical interest that this man, who suffered from severe asthma, was free of symptoms for three months after this treatment. When the asthma returned, the treatment was repeated with improvement which lasted a few weeks. The method was discontinued, however, as being excessively wasteful of penicillin.

3. *The Tent Method.*—Here, an attempt was made to conserve the aerosol by confining it in a tent which covered the head and thorax of the patient. Originally an oxygen tent was used, but subsequently a lighter, portable tent of a transparent plastic material was substituted.[12] It measured 28 by 28 by 48 inches (71 by 71 by 122 cm.), which allowed the edges of the tent to be tucked under the mattress and provided enough space for the patient to sit erect, if desired (fig. 3). The aerosol was blown into the tent through an aperture which was left open for adequate ventilation. Oxygen was not administered. The aerosol was not blown directly toward the patient, as in the open method, but rather into the tent for general distribution. The distance between the patient and the aerosolizer was about 24 inches (61 cm.).

An aqueous aerosol of penicillin was used, and the patient was kept in the tent for three hours (table 2).

Comment: Rather high and prolonged levels of penicillin in the blood were obtained by the micromethod of Fleming, as compared with the levels obtained by the macromethod of Randall, Price and Welch. Penicillin in aqueous solution did not form a stable aerosol, as evidenced by the fact that the mist produced by the aerosolizer disappeared within about ten minutes after it was blown into the tent. Examination of the inner surface of the tent showed that much of the aerosol had condensed.

In a second series of experiments with the tent, an attempt was made to stabilize the aerosol by dissolving the penicillin in propylene glycol. That stabilization was achieved was proved by the duration of the mist in the tent, partially hiding the patient from view and lasting for about one-half hour. The degree of condensation in the tent was less than that observed after the use of an aqueous aerosol. The stability of the aerosol is further reflected in the high and continuous levels of penicillin in the blood (table 3).

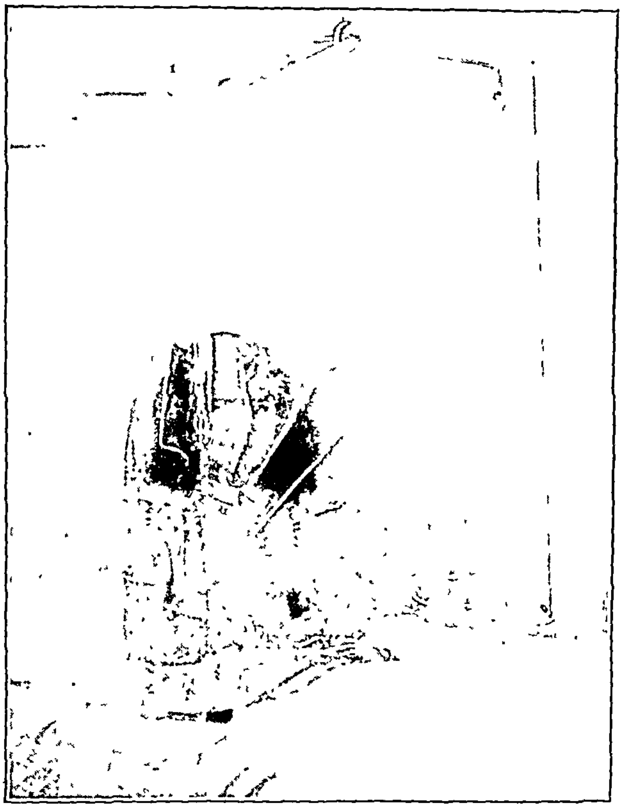

Fig. 3.—Portable translucent plastic tent for the administration of aerosol penicillin-propylene glycol

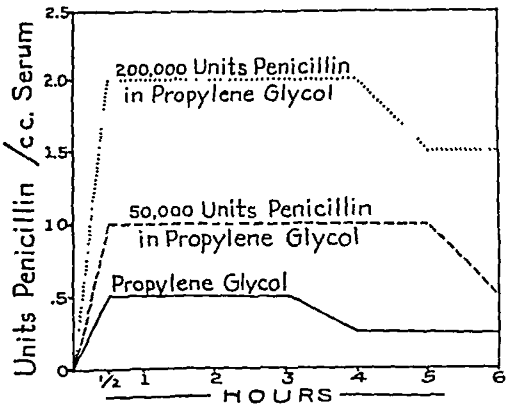

Fig. 4.—The effect of propylene glycol on the level of penicillin in the blood attained by inhalation from the breathing box.

Originally, the patients were kept in the tent for three hours, but later confinement for one hour proved sufficient. The temperature in the tent reached 90 F. and the humidity was 90 per cent during the period of aerosolization (fifteen to twenty minutes), but both fell rapidly as the steam was discontinued.

Comment: In evaluating penicillin blood levels, it must be remembered that we are dealing with a biologic, and not a chemical, test, which therefore is subject to many factors of error. There are variations in sensitivity of the testing organism, although the strain of Bacillus subtilis used in the method of Randall, Price and Welch is believed to be fairly constant in its response to penicillin. Then again, both testing methods employed in these experiments are dilution methods and are, therefore, subject to errors of 100 per cent or more. With this in mind, it can be reconciled that a higher penicillin blood level was obtained by the same patient (D.) inhaling the aerosol of 200,000 units of penicillin in the tent for one hour, than when in the tent under the same conditions for three hours. Contradictions of this type are noted frequently in determinations of penicillin blood levels.[15]

The conclusion can be drawn from the foregoing experiments that the use of a combined penicillin-propylene glycol aerosol under a tent provided a means of obtaining rapid and prolonged levels of penicillin in the blood. This method should be of particular value in the treatment of infants and children when frequent or continuous injections of penicillin are indicated.

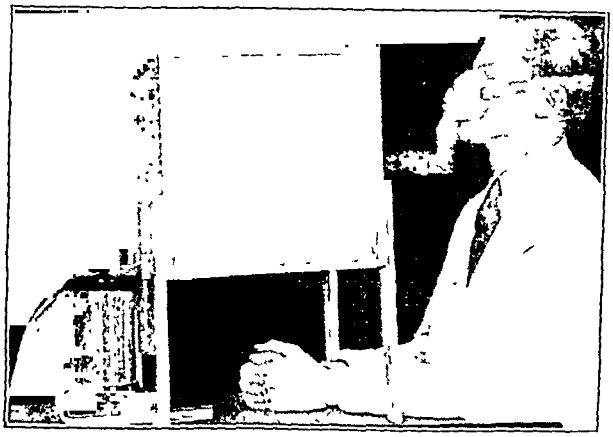

Fig. 5.—Breathing box used in administration of aerosol penicillin-propylene glycol.

4. *The Breathing Box.*—In view of the fact that some patients found the temperature and humidity of the tent uncomfortable, particularly in the summer, another method of conserving the penicillin aerosol was devised. This consisted of a box[12] into which the aerosol was blown, and from which the patient inhaled by means of a tube and mask (fig. 5). The box was made of plywood (metals increase condensation and destroy penicillin), which was treated on the inside with a water repellent to prevent the moisture from soaking into and warping the wood. The box was made air-tight except for a small aperture in the back, through which the aerosol was blown, and an opening in the front, through which inhalation was effected by means of a rubber tube and face mask. The mask was of the army aviator type, with a butterfly valve. Another valve between the mask and box permitted inhalation from the box but not exhalation into it, thereby avoiding an accumulation of carbon dioxide.

[15] Cooke, J. V., and Goldring, D.: The Concentration of Penicillin in Various Body Fluids During Penicillin Therapy, J. A. M. A. 127: 80 (Jan. 13) 1945.

The legs of the box were of unequal length, so that it tilted toward one corner; this enabled the condensed aerosol to flow toward that corner, from which it could be collected (by means of an opening in the bottom) for the purpose of assay and for reaerosolization if desired.

The treatment lasted about one-half hour. It took about fifteen minutes to nebulize the penicillin and propylene glycol (19 cc. of propylene glycol was used, to which was added 1 cc. of glycerin to further stabilize the aerosol). The rest of the time was spent in consuming the contents of the box. The patient knew that he had exhausted the aerosol when the inhalation became considerably cooler and did not have the sweetish taste of the propylene glycol. Boxes of several sizes were tried. The best and most consistent results were obtained with the box measuring 12 by 12 by 12 inches (30 by 30 by 30 cm.), because it offered less surface for condensation of the steam and aerosol. The results obtained by this method are recorded in table 4.

By the use of the breathing box and penicillin in propylene glycol, 2 patients were treated, and blood studies were undertaken to determine how quickly the penicillin reached the systemic circulation, at what moment the peak concentration was reached and how long the penicillin remained in the blood. The data are recorded in table 5.

Comment: Unquestionably, the breathing box was a distinct improvement over the methods previously mentioned. With it, effective levels of penicillin in the blood were quickly achieved (the peak was reached in thirty minutes) and were maintained for six hours. Indeed, such levels suggested the possible utilization of this method for the treatment of bacteremias and infections elsewhere in the body as well as of bronchopulmonary diseases

The breathing box conserved the penicillin-propylene glycol aerosol; nevertheless, some of the mixture condensed along with the steam in the box. The recovered condensate was still potent and could be reaerosolized, when desired. In two instances assays indicated that about 60 per cent of the penicillin remained in the condensate. Further studies with these condensates and on the results from reaerosolization are contemplated.

Control studies with aerosols of propylene glycol and glycerin, respectively, revealed that the former exerts some antibiotic activity in the blood when inhaled (table 4).

THE ANTIBIOTIC ACTIVITY OF PROPYLENE GLYCOL IN SERUM

Such unusually high and prolonged levels of penicillin in the blood were obtained in the experiments previously recorded that an explanation to account for them was sought and found in the behavior of propylene glycol. This chemical was chosen primarily because it is a good solvent for penicillin and because it produces a stable and long-lasting aerosol. Control studies (tables 4 and 6) indicated that the inhalation of this solvent imparted to the blood certain properties capable of destroying B. subtilis, the test organism.

Likewise, intravenous and intramuscular injections of 6 cc. of propylene glycol displayed the same phenomenon. The oral administration of propylene glycol in 2 instances did not impart any inhibiting action to the serum (table 6).

In vitro dilution studies of propylene glycol, to be reported elsewhere,[16] have indicated that whereas untreated human serum showed no antibiotic activity and the undiluted drug repeatedly displayed only slight antibiotic activity (equivalent to 0.031 penicillin units per 1 cc.), when it was diluted with serum in proportions of 1:10 to 1:10,000,000 all the dilutions showed an increase of antibiotic activity to 0.25 penicillin unit per 1 cc. Dilutions beyond this point displayed no bactericidal activity. Completely negative values were obtained by diluting the propylene glycol with water and with broth. Apparently, the propylene glycol and serum mixture, and not physical dilution, is the important factor.

These observations were not anticipated, although the bactericidal properties of the glycols in aerosol and in vapor form had been previously demonstrated by Robertson and his co-workers.[17]

Investigations are being continued to elucidate further the antibiotic properties of serum and propylene glycol mixtures, and to determine whether the same effect is exerted on organisms other than the one used in these tests (B. subtilis).

The studies on the penicillin level of the blood which have been recorded herein are not invalidated, however, by these observations of the effect of propylene glycol on serum. It will be noted in figure 4 that keeping the amount of propylene glycol constant and increasing the amount of penicillin increased the levels of penicillin in the blood. Propylene glycol contributed only a part of the total values obtained. Propylene glycol, therefore, not only is a good vehicle for the penicillin aerosol but serves as an adjunct in increasing the antibiotic properties of the blood.

COMMENT

The steam aerosolizer employed in this investigation has a number of features which make it preferable to other methods of aerosolization now in use. It is small, easily handled and inexpensive. Self administration of an aerosol can be quickly learned.[7a] It is possible, as well, that the warmth and moisture which the apparatus imparts to the aerosol enhances its absorption. The penicillin aerosol produced by this device is better tolerated by some patients than the aerosol produced by the oxygen nebulizer method. It is possible, in addition, to utilize this apparatus for mixed aerosol therapy. Combinations of theophylline ethylenediamine and penicillin have already been employed.[7a] Mixtures of sulfonamide compounds, penicillin and perhaps other chemotherapeutic agents, when aerosolized, should be highly effective in the treatment of respiratory infections.

To assure adequate utilization of an aerosol it is important to stabilize it and to conserve it by confinement. The formation and stability of a given aerosol, according to Abramson,[18] depend on the vapor pressure, the size of the droplets produced, the density of the material and its surface tension. Aqueous aerosols are ordinarily unstable unless other chemicals, such as glycerin, propylene glycol, urea or potassium chloride, are added.[18] It would seem, therefore, that the choice of propylene glycol as a solvent for the penicillin was a happy one. Not only did it produce a stable aerosol, but it contributed to the antibiotic properties of the blood as well. The stability was enhanced when glycerin (5 per cent) was added to the solution of penicillin and propylene glycol.

[18] Abramson, H A.: Improved Inhalational Therapy of Asthma, Arch Phys Therapy **21**: 612, 1940.

From the observations here reported, the maximum utilization of the aerosol was achieved by the use of the breathing box. This device prevented the dissipation of the aerosol into the atmosphere. The patient inhaled it at leisure. Clinically, it has been effectively employed by one of us (S. J. P.) in the prevention and treatment of sinus and bronchopulmonary infections.[19] Further conservation of the aerosol can be achieved by collecting the condensate and reaerosolizing it.

The tent method of confining the aerosol likewise proved effective. Thus, confinement of the patient for one hour in the tent provided effective penicillin blood levels of six hours' duration when using the penicillin-propylene glycol aerosol. This method should be particularly effective in the treatment of infants and children. The high humidity and temperature is objectionable, however, to some patients. Others tolerate it well. The transparent, lightweight, plastic tent employed in some of these studies is a decided improvement over the heavy, cumbersome and expensive tent devised for oxygen therapy. The problem of claustrophobia is greatly reduced by its complete transparency.

The method employing open inhalation of an aqueous aerosol, although wasteful of the aerosol, has the advantage of simplicity. Effective blood levels of penicillin have been obtained by this method, but these were of short duration. It should make a decidedly effective method of treatment in the home, when the cost of the drug is not prohibitive. It has been effective in the treatment of asthma, by the inhalation of theophylline ethylenediamine and ammonium chloride in aerosol form.[7a]

The air-tight chamber as a means of confining the aerosol gave, by comparison with the other methods employed, such poor results that the studies were limited to a single case. Knott and Clark,[2b] utilizing an electrically driven generator, nebulized penicillin into a closed chamber and demonstrated inhibition of the growth of organisms on an agar plate. Penicillin was detected (in both blood and urine) in subjects confined to this penicillin environment within fifteen minutes of exposure. These authors suggested this procedure as a means of controlling air-borne infection and for the mass treatment of infants and children in need of penicillin therapy. Sterilization of the atmosphere and prevention of cross infection can, however, be attained more economically and effectively by the use of glycol vapors [20] and ultraviolet radiation.[21]

The antibiotic properties imparted to the blood following inhalation of propylene glycol aerosol were not anticipated, in view of the observation of Robertson and his co-workers in their studies of the bactericidal properties of propylene glycol in liquid form.[17] They observed that, although this liquid revealed rather low germicidal properties, except in concentrations of 80 to 90 per cent, the aerosol was highly effective in concentrations of 1 Gm. of propylene glycol in 2 to 4 million cubic centimeters of air. The vapor of propylene glycol was even more effective, 1 Gm. in 10 to 20 million cubic centimeters of air sterilizing the atmosphere almost instantly against a variety of organisms and the virus of influenza. The lethal action of the glycol in vapor form was explained by the unusual affinity of this glycol for water, with which it is miscible in all proportions. When the vapor came in contact with an organism, it quickly reached a concentration of 70 to 80 per cent within the organism and thereby exerted its lethal action.

The foregoing does not seem to account for the phenomenon observed when propylene glycol is mixed with normal human serum or plasma. Apparently, a combination of the glycol and some factor in the serum is effected, which results in antibiotic activity of a degree possessed by neither. (Dilutions of one part glycol to ten million parts of serum inhibited the growth of a strain of B. subtilis.) Further investigations with serum and propylene glycol mixtures are in progress.

A comparison of the levels of penicillin in the blood obtained in this investigation, when using propylene glycol and the tent or breathing box, with those reported by others [2c] in this field reveals unusually high and prolonged blood levels. In a measure, this is accounted for by the antibiotic activity which propylene glycol imparts to the blood. It was observed, for example, that when propylene glycol (6 cc.) was injected intravenously (table 6), the antibiotic activity of the serum assayed in thirty minutes was 1 Oxford penicillin unit. This value persisted undiminished for the four hours of testing. This evidence of prolonged activity of the glycol may account for the sustained blood levels recorded in tables 3 and 4.

It is of interest to note that Hanzlik and his associates [22] reported that dogs continue to eliminate propylene glycol in the urine for twenty-four hours after a single dose. This delayed excretion of the drug should enhance its effectiveness as an antibiotic agent.

Initially, Fleming's micromethod [9] for penicillin assay, in which a hemolytic streptococcus (strain C 203M) is the test organism, was used in these studies. It was convenient for this type of study, since only a few drops of blood obtained from the finger were needed. This method revealed such high levels of penicillin in the blood that it was decided to check the results by employing another method.

The method devised in the laboratories of the Bureau of Food and Drug Administration by Randall, Price and Welch,[10] utilizing B. subtilis as the testing organism, was considered more reliable because it provided a sharp end point and the organism employed was both sensitive to penicillin and easily cultivated. This method was employed in the major part of these studies, despite the disadvantage of repeated venipunctures.

A comparison of the results obtained by these two methods show some degree of parallelism, although lower penicillin blood levels were recorded throughout with the Randall procedure. With the exception of the studies with aqueous aerosols of penicillin by the tent method (table 2), the results obtained with the Fleming procedure were corroborated. The original impression that prolonged and effective levels can be obtained in the blood by inhalation of combined penicillin-propylene glycol aerosol was confirmed.

(b) Hanzli [illegible] I.; Van Winkle, W., Jr., and Kennedy, N. K.: [illegible] Glycogenic Action of Propylene Glycol and Some [illegible] 67: 114, 1939.

The penicillin blood levels reported here must be considered not as absolute values (in view of the technical difficulties in obtaining accurate levels) but rather as an index that the aerosol method employed in this investigation is capable of providing therapeutic blood levels of considerable duration.

Unquestionably, in view of the facts here recorded, the diluent propylene glycol accounts in part for the high levels of penicillin in the blood. Another contributory factor which possibly accounts for the high blood levels obtained may be the use of steam. It may facilitate the absorption of penicillin by moistening and warming it as it is aerosolized.

One other factor must be considered in the interpretation of these prolonged blood levels, and that is the possibility of the retention of some of the penicillin somewhere in the bronchopulmonary system (in the alveoli or in nonfunctioning capillaries) from which it is gradually released. This is suggested by the results obtained with simple inhalation of aqueous aerosol of penicillin (table 1) in patients A. 1 and A. 2, in whom, after a zero level at the one hour interval, levels of 0.032 unit were obtained at the one and a half hour interval. The same phenomenon was noted in patients C. 1 and C. 2. Similar conclusions resulted from studies with aerosols of sodium sulfadiazine (Prigal and Speer[23]) in which prolonged blood levels were obtained after fifteen minutes of inhalation of 50 cc. of a 5 per cent solution of that drug. Chapple and Lynch reported similar results and concluded that the lung acted as a depot.[24] These observations need confirmation and, if corroborated, would emphasize the impression obtained from these studies that the lung is an excellent avenue for the introduction of medicaments intended for systemic dissemination.[1b]

The capacity of the lungs for absorption is explained by the fact that there are an estimated 300 million alveoli in the lungs, lined by capillaries which have the thinnest wall in the body ($\frac{1}{30,000}$ of an inch, or 0.00008 cm., thick), thus providing an estimated surface of 700 square feet (65 square meters) for absorption.[25]

The prolonged penicillin blood levels of therapeutic value described herein suggest also the possibility of treating nonpulmonary infections (systemic or localized) by inhalation instead of injection, in cases in which prolonged and continuous treatment with penicillin is indicated. The need for repeated painful injections or the troublesome continuous intravenous drip may thus be obviated. This should be of particular value in pediatric practice.

The use of mixed aerosols, which is feasible with this aerosolizer, opens up the possibility of the clinical application of these aerosols when the infection is of the mixed type and is not responsive to a single agent. Sulfonamide drugs, penicillin, streptomycin and other antibiotics can possibly be used in various permutations and combinations.

SUMMARY AND CONCLUSIONS

1. A combined steam generator and aerosolizer is described, which effectively produces aerosols of penicillin whose inhalation is capable of providing good therapeutic levels of this agent in the blood.
2. Penicillin dissolves readily in propylene glycol to form an effective, stable aerosol. The addition of glycerin (5 per cent) further stabilizes the aerosol.
3. Methods of conserving the aerosol for maximum utilization include simple open inhalation; inhalation within an air-tight chamber or transparent portable tent, and inhalation from a breathing box.
4. Unusually high and prolonged levels of penicillin were obtained in the blood when a penicillin-propylene glycol aerosol was inhaled within a tent or from a breathing box.
5. The tent method should be ideal for the treatment of infants and children or whenever continuous treatment with penicillin is indicated.
6. Propylene glycol, by inhalation of its aerosol and by intravenous or intramuscular injection, imparts to the blood serum a pronounced inhibitory action against a strain of Bacillus subtilis (an attribute not possessed individually by either the propylene glycol or the serum).

PSYCHOGENIC FACTORS IN PELVIC PAIN

WILBUR R. MILLER, M.D.
Iowa City

In discussion on the subject of emotions and thought processes with medical students, I stress that much thinking is uncritical and emotionally determined. As an illustration, the students are asked for their concept of pain, as one of the symptoms most commonly met in the eliciting of complaints from patients. The usual response is to describe it as a neurophysiologic process caused by overstimulation. I counter with the statement that it is the conscious perception of such a process and that without consciousness it does not exist. Furthermore, under special circumstances it does not exist when consciousness is present. A member of the class is then called to the front and placed under hypnosis, given the suggestion that he will not feel pain and then asked to open his eyes. It is demonstrated to the class that he is fully aware of what is going on about him. Next, a sterile needle is pushed through his skin; he shows no sign of pain, denies that he feels it and manifests an obvious interest in the phenomenon. He is then put back to sleep and given the suggestion that he will feel pain. When the experiment is repeated his reaction is the expected one to such a stimulus. The students eagerly question him afterward, and his obvious sincerity convinces them that he had not felt the pain when told that he would not.

For some reason this demonstration disconcerts many of the students, because they feel they must revise their concepts of pain and their evaluation of it in their patients. I feel that such an attitude is a healthy one, and I follow this with a discussion on the emotional and psychogenic causation of pain and its relationship to the practice of medicine.

I hope that these students will remember in their practice of medicine that pain does not always mean

---

Professor and Head of the Department of Psychiatry, State University of Iowa College of Medicine; Director, Iowa State Psychiatric Hospital.

Read in a symposium on "Pelvic Pain" before the joint meeting of the Section on Obstetrics and Gynecology and the Section on General Practice of Medicine at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 5, 1946.

organic pathologic conditions. One quickly learns in psychiatry that there is an "organ language." For ages people have expressed emotional reaction in terms of their bodily organs. How common and readily understood are such expressions as "heartache," "pain in the neck," "to have guts" and "my hair stood on end." Is there any doubt in one's mind but that such modes of expression grew out of the recognition over the years that emotional reactions can give rise to organic sensations and even discomfort? In this scientific age in which even the layman has more access to medical knowledge than did the medical student of fifty years ago, the average patient has extended his "organ language" to include medical and pathologic expressions.

There is an obvious reason why special areas of the body should be elected as the seat for the expression of certain emotional disturbances. The cardiovascular system is usually the structure for denoting anxiety and fear, because normally it is involved in those emotional states. The gastrointestinal system often is the site of reaction to states of disgust, aversion and deprivation, for such emotional states are commonly associated with the securing or rejection of food. So the pelvic contents, particularly the genitourinary system, is the site of reactions to sexual and marital difficulties.

It is generally stated that only 1 of 3 married women are adequately adjusted to marital relations. In psychiatric practice one often finds that many of these women have little awareness that they are poorly adjusted. They have been educated to believe that it is normal and nice not to have a sexual response. Therefore their maladjustment is not expressed in terms of maladjustment but in terms of "organ language" and symptoms.

During the war years I treated a large number of war wives whose husbands had been away from home for periods up to two and three years. There seemed to be two common factors in their seeking help—general emotional problems related to the separation and the discovery that their marriage had not been as successful as they had supposed. Both these factors tended to emphasize previous dysmenorrheas or other pelvic complaints. In 1 such case dysmenorrhea became greatly exaggerated. Previously the woman had been treated with hormones, with only temporary relief. Interviews brought out a sexual incompatibility with the husband and a lack of ability to achieve sexual orgasm. This was based on a building of resentment because of his overbearing attitude and domination. The conscious facing of this situation brought about a lessening of tension with a disappearance of symptoms. With his return, although the dysmenorrhea did not recur, she was still unable to respond sexually. However, she felt that with her understanding of the situation she could maintain the marriage and handle her reactions more satisfactorily.

The criticism should be raised as to what medical evidence psychiatrists can present in cases of this kind that emotional disorders can or do produce a dysfunction which gives rise to complaints. I think that many writers on psychosomatic subjects are making claims that cannot be verified by experiment. As yet, I know of no clear-cut experiment showing that emotional disorders have produced gastric ulcer, colitis or dysmenorrhea. On the other hand, I doubt if there are very many experimental demonstrations that retroversion or floating kidneys are responsible for the many disorders attributed to them.

In a recent article in THE JOURNAL A. E. Bennett[1] of Omaha reported on 150 patients who finally came to his psychiatric clinic. The 121 women had had a total of two hundred and five surgical treatments and three hundred and sixty-eight medical treatments before their disorder was recognized as psychiatric in nature. Is not this a reflection on the diagnostic acumen of the members of the medical profession? Perhaps as a psychiatrist I am now in a position of advantage. I don't see the patient until all the rest of the physicians have made their mistakes. But supposing in the future that patients consult a psychiatrist first, much as they do an internist now. I rather expect that some fairly obvious surgical and medical conditions will be missed. Let me give an example from an experience I recently had.

A young faculty wife was referred to me by a local woman physician with the statement that the patient had been unable to have normal sex relations with her husband for seven years. The physician furthermore stated that she had made a pelvic examination with great difficulty because of the patient's fear and vaginismus. I found the patient to be an intelligent young woman who was convinced in her own mind that her condition was psychogenic in nature. I attempted a pelvic examination but because of the patient's great resistance was not able to complete it. Instead of referring her to the department of gynecology and having her examined under anesthesia, I went on the observations of the local physician. Treatment was started. After four or five visits I came to the conclusion that I was equally unsuccessful in finding any emotional conflicts of a sexual nature at the basis of the vaginismus. I told the patient so, and then she suggested that since her uncle was a gynecologist she thought she would like to visit him in New York and have him examine her. I gladly consented. In two weeks she returned with the report that he had examined her under anesthesia and found an imperforate hymen. She also reported that she had been able to have sex relations with her husband. All I can say to soften the blow is that I believe my psychiatric treatment was less harmful to the patient than improper surgical intervention would have been. The patient supported this by saying that although the psychiatric interviews had not cured her difficulty, it had given her courage to go to her uncle and have a thorough pelvic examination. I am still not sure that she meant the statement only to ease my feelings.

The main point is this: The knowledge of the patient and her feelings are just as important in making a diagnosis as is a thorough knowledge of physiology and anatomy. One cannot do without either, yet I think it will be agreed that the medical educators in the past have sadly neglected teaching students much about the person as a human, living and emotional organism.

However, this is not entirely the fault of education; much blame lies with the physician himself. Many will not take the time or trouble to do the one fundamental act that is absolutely necessary in any kind of diagnostic procedure, that is: take an adequate history. That does not mean sitting down and asking the patient a routine set of questions but means finding out something about the man or woman. The only difference between a psychiatric history and a medical history is that the psychiatrist has to find out something about the person.

---

[1] Bennett, A. E.: Faulty Management of Psychiatric Syndrome Simulating Organic Disease, J. A. M. A. **130:** 1203-1208 (April) 1946.

One must always remember that there is an organ above the neck called a brain and that it has been active since early childhood. In fact, in childhood it probably received its most vivid and important impressions, which will determine the attitude of its owner for life. Is there any reason why it is less important to learn that Mary Smith acquired a lasting hate for men because she was treated cruelly by a drunken father than to learn that she had "measles, mumps and chickenpox before the age of 10?" For gynecologists it may be a much better clue to the understanding of her frigidity in marriage than any other item in the examination. It is well to remember that sexual function is more closely related to the powerful emotion of love than to any other. And as far as I know, love still seems to have a universal appeal. When it is interfered with and the woman is unhappy, depressed, worried and frustrated, it is more than likely that its physiologic counterpart will reflect most of the disturbance.

May I suggest humbly that pain is what the patient thinks it is, and the only clue that one has to whether the patient feels pain is what she says about it. If in a careful gynecologic examination one finds signs and evidence of a process that could and most probably does give rise to pain, then certainly one's most skilful medical or surgical treatment is indicated. But I should like to suggest that if such observations are not made there is an equally likely source of pain—that caused by the associated physiologic disturbances which accompany *emotional maladjustments of long standing*.

H. B. Atlee [2] presents this problem from the point of view of the gynecologist. He is much more critical and faultfinding with his colleagues than I could consider to be my right. Never having performed a gynecologic operation, whether indicated or not, I am inclined to accept his advice that in patients with chronic right-sided pain there is no need to hurry. The patients have had their difficulty for a long time, and before surgical intervention is resorted to, as in an emergency, there is no harm in looking into some other aspects of the patient's life as possibly contributory to the complaint, if not causative. Psychiatrists see too many patients with abdominal scars and histories of eviscerations to believe that there is only the surgical approach.

May I conclude by making this plea. One should be a physician first—a surgeon, gynecologist, internist or psychiatrist last. The primary interest is in making the patient well, not in proving that one's method is the only approach. There is nothing mysterious or difficult about most psychiatric practice, but it does take an interest in persons and their troubles as well as a technical and scientific knowledge about their anatomy and physiology. I was delighted when the dysmenorrhea of a patient of mine who was found to have hypothyroidism cleared up immediately (and has remained cured for five years) as a result of thyroid medication. It was so much simpler and easier than an investigation of her personality. Everyone likes to avoid hard work and prefers to deal with direct tangible facts. That is why I shall always do a complete history, physical and laboratory investigation first before embarking on a psychologic investigation. It is easier and more easily verifiable, but to neglect the latter is not excusable, any more than embarking on highly questionable medical or operative procedures can ever be good medicine.

ABSTRACT OF DISCUSSION

Dr. William G. Barrett, San Francisco: I think Dr. Miller has stated clearly the problem which psychiatrists often face in dealing with gynecologic symptoms and the psychologic problem which gynecologists face when they come up against the symptoms of pelvic pain. I might say a few words about the term psychosomatic that so much has been heard about. At this meeting I met some friends whom I hadn't seen for quite a while, one a pediatrician and the other an internist. They both told me independently that they thought that soon *they would limit their practice to "psychosomatic medicine"!* That is a serious misconception of the meaning of the term psychosomatic. One cannot specialize in psychosomatic medicine. The term in its current usage was devised by a group of psychiatrists who had been working with the problems of chronic disease and who had been impressed anew with the fact that the mind and the body are one, not separate. Every emotion is reflected in physiologic changes, and they noted that emotions which existed chronically and which did not achieve proper expression often produced a chronic physiologic malfunctioning. The term psychosomatic describes a point of view: the study of the role of emotion in various disease processes. The problem raised by Dr. Meigs in his discussion of the previous paper, real pain versus psychic pain, has been quite well dealt with by Dr. Miller. In my opinion the problem is one of localization and the degree of disturbance of function There can be no question of "real" versus "psychic" when it comes to pain. Really to utilize this conception, this approach which is described by the term psychosomatic, one must think rather carefully to maintain the unity of mind and body. It must be remembered that change of structure is not always *the primary cause of change of function. The mind also can* alter function, and it is now known that prolonged changes of function can result in structural change. This fact reverses the earlier conception and, I feel sure, introduces an extremely important element into medicine as a whole—into the practitioner's way of thinking of disease.

Dr. Dorothy L. Morse, San Francisco: An old common sense treatment has been wrapped in new paper and has been called psychosomatic. Physicians must aspire to achieve good results whether aided by "psychology," as they were apt to say, or by psychosomatic treatment. Dr. Miller is to be commended on his sane approach to this complex problem of pelvic pain. His psychiatric point of view of pain in the pelvis is heartening, as he holds to no one-sided mode of tackling the causation of the problem or its treatment. He stresses: (1) an adequate history and examination to determine a physically abnormal process or a physiologic disturbance associated with emotional adjustments; (2) treatment of the person with a disease, not the disease in a person, and (3) that one must be a physician, a healer in the broad sense, first and a surgeon, gynecologist, internist or psychiatrist last. Dysmenorrhea, dyspareunia and pelvic pain are a worthy triad to stir the gynecologist, who should know when to supplement gynecologic therapy with psychotherapy. Probably he feels that he cannot take enough time to listen to patients talking at length, hoping to get fears and problems "off their chests." Too many pelvic operations have needlessly been performed, and many a scar has been made when the underlying cause could not be approached with a scalpel. Weiss and English state that personality traits and reactions are determined by the action of the endocrine glands and that any disturbance in the personality may upset the function of the glands, thus leading to real subjective symptoms. The emotional life has much to do with illness. In 1944 Haman studied 400 subjects in Brookline, Mass., with reference to pain thresholds. He showed that in dysmenorrheic women there is an intrinsic factor which renders them more susceptible to pain than those women free from dysmenorrhea. When the dysmenorrheic woman is assured that no organic disease exists, her fears are allayed and further treatment with suggestion, sedatives or analgesics proves beneficial. Premenstrual tension is viewed by the gynecologist as an unbalanced hormonal and electrolytic process, by the psychiatrist as an expression of emotional upset. The answer is probably an overlapping of the two ideas. Dyspareunia and frigidity may have a physical basis, but frequent unhurried discussions will establish confidence and finally unearth emotional maladjustments. Perhaps the trouble is associated with a firm hymen, fear of pregnancy, improper approach of the husband or fears due to lack of or wrong family advice. Just to unburden her thoughts to a sympathetic physician is often sufficient to lead the patient to an understanding of her illness.

---

[2] Atlee, H. B.: Chronic Right-Sided Pain in Women, Canad. M. A. J. 53: 122-128 (Aug.) 1945.

Dr. Wilbur R. Miller, Iowa City: I had the great pleasure of working with the secretary of this section, Dr. Mengert, a number of years ago, and I feel that he kept me pretty much down to earth when it came to dealing with such problems. Psychiatrists are popular subjects for cartoons these days, and perhaps they are getting a little bit sensitive about it, but Dr. Morse pointed out one factor of some importance and I am glad that she stressed it. Dr. Barrett also brought out the same point. It is that psychosomatics is an unfortunate term, and it has only clothed an old idea in a new dress. The term itself clears up none of the trouble "Psychosomatic" is still a hyphenated term despite leaving out the hyphen. Most workers in academic psychiatry are trying to get closer to medicine in general, trying to get away from the former isolation of psychiatry. Medical students and interns find many aspects of psychiatry that are directly applicable to every day medicine.

FERTILITY STUDIES OF THE MALE IN BARREN MARRIAGES

LEWIS MICHELSON, M.D.
and
ROBIN MICHELSON, M.D.
San Francisco

Sterility as defined by Meaker "is the inability to initiate the reproductive process." Infertility he defined as "an all inclusive term embracing any degree of conceptive capacity below the level of physiological perfection." We prefer the use of the term "lowered fertility."

The exact incidence of barren marriage is difficult to determine. Most authorities believe that between 10 and 15 per cent of adult marriages are barren. In these the male is either a contributory or sole cause in 30 to 50 per cent of the cases.

Clinically it is easy to label a marriage "barren" if defects are found which would obviously prevent conception. However, in those couples in which only a reduced fertility, and not an absolute sterility, is found, it is difficult to establish exact criteria for barrenness. In this there has been considerable disagreement, and consequently we have had to be more or less arbitrary in our selection of cases.

In our series we have accepted the opinions of Meaker,[1] Rich Hammen,[2] Wharton [3] and others, that a couple must have been trying unsuccessfully to produce a child for one year or more before the marriage can be considered barren. We have included other cases, regardless of the "involuntary sterility period," in which in our opinion defects existed which would prevent conception. These obviously would include cases of azoospermia or other serious defects of the spermatozoa or the semen; faults preventing the delivery of the semen and certain female faults, such as blocked tubes, absent ovaries and nonovulatory cycles.

The number of barren marriages in the group thus selected total 855, which we are herein reporting.

The causation of reduced fertility in the male is not known for the great majority of cases in our series. There were 519 men with impaired fertility. In 393, or 76 per cent of this group, we could not determine the cause of the subfertility.

The impairment in fertility may be due to a constitutional or local pathologic factor, or factors.

Among the constitutional diseases occurring in our series there were 9 patients who had had syphilis. In 3 of these the sperm count was below normal. One of us (L. M.[4]) found in a survey of 100 men, of whom 50 had had syphilis and 50 were normal healthy males, that there was no appreciable difference in the fertility of the two groups. We consider that unless some local lesion which involves the liver, testicle or epididymis has been demonstrated in syphilis, this disease does not affect fertility. As this was not the case in any of these patients, syphilis is not included as a cause of infertility in our series.

Tuberculosis had been present in 8 cases, but in only 1 do we believe that this disease was the cause of the low fertility. This man had had a tuberculous epididymitis.

Three patients gave a history of malnutrition. In 2 of these a bilateral gonorrheal epididymitis was the cause of the infertility, the testes being normal.

Fröhlich's syndrome accounted for 2 cases of azoospermia.

The etiologic basis was determined in 87 patients, or approximately 16.8 per cent of the 519 men with reduced fertility. Thirty-nine additional patients gave a history of only unilateral disease or injury to the testicle or vasoepididymal duct. This in conjunction with a pathologic condition of unknown origin on the opposite side resulted in defects of the spermatozoa sufficient to produce impaired fertility. It is probable that in many of the patients the inflammatory process which appeared to attack only one side was also present in the opposite organ in such a mild form that the symptoms were not observed. The cases in the two groups totaled 126, or approximately 24 per cent of the series.

Bilateral gonorrheal epididymitis was present in 26, or 20.6 per cent of the 126 cases; bilateral genital trauma in 24, or 19 per cent; bilateral orchitis due to mumps in 13, or 10.3 per cent, and bilateral abnormal genital development in 12, or 9.5 per cent. These four causes accounted for 75 cases, or 59.6 per cent of the cases in the two groups. Table 1 classifies the causes of infertility of the patients in whom there was a known etiologic condition. Table 2 classifies those cases with a unilateral known cause. It is probable that in most of the cases of infertility listed as occurring in patients with only a unilateral known etiologic basis there had been such slight involvement of the apparently unaffected apposing organs as not to have been demonstrable.

The diagnosis of lowered fertility in the male has for its basis the analysis of the semen and particularly a study of the spermatozoa. A careful physical examination and clinical history must be included for the final evaluation of the factors causing the subfertile state.

Scientific study of the semen has progressed greatly during the last decade, owing to the work of Moench, Hotchkiss, Cary, MacComber and many others. Today there are certain standards that are generally accepted as criteria, within certain broad limitations, which are indicative of normal male fertility

TABLE 1—*Reduced Fertility (Male) with Known Etiology*

Pathologic Condition *	Azoospermia, No of Cases	Other Sperm Defects, No of Cases	Total	%

Total	69	18	87	16.75

* In 87 (16.8 per cent) of 519 cases

A complete and thorough discussion of the qualifications requisite for normal fertile semen is not within the province of this paper. However, for an understanding of the data on semen in the series reported here, a few generally accepted facts may be stated.

The normal fertile man usually ejaculates from 2.5 to 6.0 cc. of semen. It is a creamy color, has a p_H of 8.0 to 8.5, a certain viscosity and a distinctive odor. Variation in these characteristics does not necessarily indicate that the person secreting it is relatively or absolutely infertile. Such deviation or deviations must be weighed in conjunction with other factors observed in the semen.

Most essential, of course, is a knowledge of the number and other characteristics of the spermatozoa in the semen. The normal fertile male's ejaculation will usually contain from 60 to 300 million spermatozoa per cubic centimeter. Of these, at least *60 to 70* per cent remain vigorously active for at least seven hours. Abnormal forms present should not exceed 20 per cent. The tapering form appears to be the one most consistently increased in number in men of lowered fertility. Moench[5] has *considered 8.5 per cent to be the* normal, any increase over this indicating impaired fertility.

Total	17	22	39	7.40

* In 39 (7.4 per cent) of 519 cases

A slight change in any of these essentials—number, motility or morphology—does not necessarily imply reduced fertility, but an extreme deviation in any one of them does.

Often, however, an opinion can be formed only after noting how much deviation is present in all characteristics.

Although these are the characteristics of the spermatozoa usually found in the semen of men able to impregnate their wives, it must be emphasized that no absolute rule can be formulated based on these observations.

In the few cases of pregnancies reported to us after we had studied the infertility problem of the couples, there were 11 husbands with a count of 20 million spermatozoa or less. Two of these had a count of 5 million each and 1 of 3 million. In 4 of these 11 cases the abnormal forms of spermatozoa were above the usually accepted percentage of 25 per cent for a normal fertile man. In 7 cases the percentage of motile cells present was under 50 per cent.

There were 146 cases of azoospermia; 35 patients with semen containing spermatozoa numbering ½ million or less per cubic centimeter and 3 with 1 million. *This group of 184 men can be designated as sterile.* They make up approximately 35 per cent of the husbands with impaired fertility, or approximately 21 per cent of all the husbands in this barren marriage series.

TABLE 3—*Relative Fertility of Husband and Wife in Two Hundred and Eighty-Seven Barren Marriages*

	No of Cases
Both husband and wife fertile	99
Both husband and wife sterile	1
Husband sterile; wife impaired fertility, not sterile	8
Wife sterile, husband impaired fertility, not sterile.	19
Both husband and wife contributing causes	16
Husband sole cause	103
Wife sole cause	41
	287

There were 29 cases with counts of 1 to 5 million per cubic centimeter and 13 cases with a 5 to 10 million count. In the remaining *202* cases of men with a count of below 60 million per cubic centimeter, it varied from 51 cases in the 10 to 20 million group to 34 in the 50 to 59 million group.

In the semen of 91 men there was a normal number of spermatozoa; but either the motility or the morphologic essentials, or both, were altered to such an extent as to warrant a diagnosis of lowered fertility.

As an aid in the interpretation of the characteristics of the spermatozoa *in the test tube specimen*, we have included the postcoital, or Huhner test. In 11 couples that showed greatly lowered motility for the male germ cells in the test tube specimen, a postcoital examination disproved this assumption, there being many active spermatozoa well up in the cervical canal.

In order to obtain satisfactory information, it should be stressed that this examination must be performed when the external cervical os is widely open, the mucus *clear and* profuse, showing few or no epithelial cells or pus cells microscopically. This is within about forty-eight hours of ovulation. In obtaining the specimens

---

5 Moench, G L Studien zur Fertilitat, Stuttgart, Ferdinand Enke, 1931.

from the cervical canal, separate samples should be taken from three or four different levels. Although this procedure does not give a completely satisfactory estimation of the number and motility of the spermatozoa present in these portions of the canal, it does give a more representative sampling of the sperm population than that obtained at the usually accepted postcoital examination.

Information obtained from the testicular biopsy specimen is of great importance in diagnosis and prognosis. However, this information must be correlated with the clinical and laboratory observations before final judgment is passed. It should be emphasized that the section may not be truly representative, because only a small piece of tissue can be taken and the histologic picture often varies in different parts of the testicle.

The following examples emphasize the importance of the biopsy specimen in confirming or disproving the impression obtained from the physical examination.

In 31 selected biopsies the physical and microscopic examinations demonstrated normal testes in 14 cases. In 11 cases the testes were normal on physical examination, but sections showed abnormal testicular tissue. In 6 cases both examinations disclosed abnormal testes.

In the ultimate analysis, production of a child by a couple is the proof that both are fertile. However, the barrenness of a couple does not demonstrate the infertility of both, nor does it show which party is incapable of procreation or the extent of the contributing factors that may be present in husband and wife.

Of the 855 cases reported here, we were able to obtain complete data in regard to the fertility of both partners in 287 cases. A study of these couples was made to determine the relative responsibility of husband and wife for the infertile union.

In viewing these data it must be borne in mind that usually the husband had been referred to us only when the wife had been examined and was believed to be fertile, or when the reduced fertility demonstrated was not felt to be enough of a factor by itself to prevent conception. However, in 41 cases disease of the female pelvic organs was present to such an extent as alone to have accounted for the failure of conception. Obviously the data assembled from such a selected group cannot be indicative of the relative fertility of man and wife for barren marriages as a whole. This study offers a challenge to physicians, in that of these 287 couples there were 99, or approximately 34 per cent, in which both husband and wife were apparently fertile, as far as could be determined (in the present state of medical knowledge), and still no pregnancy occurred.

In 127, or approximately 44 per cent of the couples, the husband was found to be either a sole or contributing factor to the infertility.

From table 3 it can be seen that either husband or wife may be the sole cause or both may have minor defects the combination of which is sufficient to prevent conception. Consequently, one must not be satisfied with the finding of defects in one partner, but both husband and wife should be completely examined before an opinion is expressed as to the factors causing the infertility and the possibility of altering them.

It is incumbent on every physician not to initiate medical or surgical procedures on the wife until there is conclusive evidence that the husband is of high enough fertility to procreate.

SUMMARY

In a study of the fertility of the male in 855 cases of barren marriages an analysis of the semen, particularly of the characteristics of the spermatozoa, indicated impaired fertility in 519 of the husbands. The cause of the impaired fertility could only be determined in 87, or 16.8 per cent, of the cases.

In 287 of the couples adequate data was collected to analyze the relative fertility of husband and wife; both were apparently fertile in 99 of these cases, and the husband was either a contributing or sole cause of the childlessness in 127.

It is emphasized that in all infertile unions both husband and wife should be completely studied.

ABSTRACT OF DISCUSSION

Dr. Henry Sangree, Philadelphia: My associates and I have had only one success in 7 vasoepididymal operations. Dr. Edward Martin, who invented the operative procedure, showed that it was necessary to use silver wire to establish a permanent opening. In our last operation we have used a fine black silk such as is employed in arterial anastomosis. We have used the small scissors and forceps which the ocular surgeons use and have performed all the operations with the patient under a general anesthesia. We do both right and left vasoepididymal anastomosis simultaneously. As all these men have azoospermia, not only do we have a microscopist in the operating room to make a search for motile spermatozoa at the time of operative intervention, but we now also do a preliminary testicular biopsy on both testes, usually some time before the epididymovasostomy. If a man has complete atrophy of the seminiferous tubules in both testes operative intervention is not warranted. In the last 3 instances we have arranged the date of the operation on the man to correspond to the time of ovulation in the wife, and if motile sperm are found an artificial insemination is performed at the time of the operation. This we were able to do only once, without success. In the first 100 men examined, 12 cases of azoospermia and 25 of aspermia were found; 8 had severe varicocele; 7 had syphilis; 2 had hypospadias, and 1 epispadias. Chronic prostatitis, which we consider a cause of infertility, was present in 21 men. A basal metabolism test is routinely performed in all cases. Twenty-one men in the first 100 examined had hypothyroidism of varying degrees. Fluhmann of California and others have developed accurate pituitary assays, especially of the anterior pituitary gland, which often causes mild degrees of endocrine disturbances resulting in infertility. The obstetrician and gynecologist have been foremost in the study and investigation of human fertility. The urologist until recent years has paid little attention to this field, for which by training and experience he is especially fitted.

Dr. Victor D. Lespinasse, Chicago: Testicular biopsy is of no clinical value. It gives no pertinent or clinically valuable information. The Bogoloff, Scaduto, Martin operation offers slight chance of success. In 1910 an operation was devised known as Direct Vasoepididymostomy in which one specific epididymal tube is joined to the vas. Around 60 to 70 per cent of the operations have been successful. The cases that do not have sperm are of two types, the nonproductive cases in which the testicle is not producing sperm. That testicle is usually small, round and nonsensitive. The patients that do not have any sperm should be subject to exploration. If the surgeon finds an obstruction in the lower part of one epididymis, he should look at the other side and see if the patient has an obstruction in the ejaculatory duct or pelvic vas so that the two vasa can be joined and the sperms can get through in that way. If the surgeon can perform a vas operation, excellent results will follow. If not, some operation has to be performed that will relieve the obstruction and usually that is a direct vasoepididymostomy (Lespinasse). The lower down on the epididymis it can be done, the better. If a vasoepididymostomy cannot be done it may be possible to perform a sac operation (Lespinasse), a fistulization of the epididymis into the tunica vaginalis, and if the man happens to have a little hydrocele so much the better, because it is a fluid for the sperm to sail around in. At the proper time the spermatocele can be aspirated and the material placed into the uterine cavity, and so achieve a pregnancy.

Dr. Edward T. Tyler, Los Angeles: In analyzing the statistics of Dr. Michelson's excellent study, one might erroneously assume that since he is a urologist he will see a relatively higher percentage of infertile males than is the average incidence in barren matings taken at random. However, in a smaller series of approximately 70 couples, referred to the Shelton Clinic as primarily gynecologic problems, major responsibility was attributable to the male in 21, and some degree of seminal inadequacy was found in 48. These figures would also tend to emphasize the importance of the male factor. One cannot accept the study of one specimen of semen as being conclusive. It is important to evaluate at least two or even three specimens from a person before forming any definite estimate as to his fertility. On several occasions repeated analyses of the semen of husbands who had previously been told they were normally fertile revealed that the specimens were highly inconsistent, varying from poor to good, under comparable conditions. Collection of a semen specimen in a condom is unsatisfactory. It invalidates the estimate of motility and viability. A specimen for examination should be ejaculated directly into a clean, dry, glass receptacle. I prefer to obtain specimens of semen for analysis at a time corresponding to the relatively infertile period of the wife's cycle. In this way there is less possibility of wasting a good specimen when it might be useful. Many infertile males lack the capacity for quick regeneration of spermatozoa, and therefore it is advisable to avoid analyses of semen near the wife's estimated time of ovulation.

Dr. Lewis Michelson, San Francisco: Dr. Sangree spoke of prostatitis as a cause of impaired fertility. Although it is known that the prostatic secretion is essential to the viability of the spermatozoa, I have never been able to observe any change in the characteristics of the sperm following treatment of the diseased gland. It is extremely probable that there are some intrinsic qualities of the germ cell that cannot be demonstrated microscopically. The fact that occasionally pregnancy occurs following treatment may point to such a conclusion. The length of involuntary sterility of the couples in this series varied from one to thirteen years. A large percentage of couples waited five years or over before consulting a physician. In many cases the wife had been treated for some time before the physician advised examination of the husband, and in some of these the husband had no spermatozoa. I want to emphasize again that in every case of infertility both husband and wife should be examined. I must disagree with Dr. Lespinasse that the normalcy of a testicle can be determined by physical examination alone. I have often seen a testicle that appeared normal on physical examination, but the biopsy specimen was abnormal. However, these small pieces are not always truly representative of all portions of the testicle. I agree with Dr. Tyler that more than one specimen of semen should be examined. This applies also to those cases in which the first specimen appears to be normal. I often examine three to four specimens before I am satisfied. I also am in accord with his opinion that a condom specimen is not trustworthy. It is the powder, not the rubber, that damages the motility of the spermatozoa. Some patients are not able to obtain a specimen except by use of a condom. In those cases the condom, before being used, should be washed thoroughly with a mild soap and water, rinsed with distilled water and dried. I have seen one case of necrospermia in over 1,100 cases of barren marriage. On postcoital examination many spermatozoa were found (at least 100 per high power dark field) well up in the cervical canal. This observation is both instructive and important, as it shows that the vibratile motion of the spermatozoa is not essential to their transport into the uterine cavity.

SURGERY OF THE LARYNX IN BILATERAL ABDUCTOR PARALYSIS

JOSEPH D. KELLY, M.D.
New York

In my opinion, more thought and interest has been shown in the surgical treatment of bilateral paralysis of the abductor muscles of the larynx since 1939 than in any other equivalent period in the history of medicine.

The reason for this interest, I believe, is the number of successes resulting from the extralaryngeal approach to this problem. The old adage that "Nothing succeeds like success" may well be applied in this instance. When the old intralaryngeal methods were being used with their attendant failures, not many were interested in trying to cure bilateral abductor paralysis by surgical methods. But when Dr. Brien King [1] of Seattle, Wash., came forward with his idea of the extralaryngeal approach to this problem, many surgeons began to do some thinking on this phase of laryngeal surgery.

The great obstacle in the intralaryngeal route was the formation of scar tissue. For 1 success, there were 10 failures. As Dr. Fletcher Woodward [2] expressed it in one of his papers on the subject, "This is not a successful operative procedure." The extralaryngeal route offered an escape from the failures of the past, and surgeons welcomed this possibility with open arms.

So to Dr. Brien King goes the credit for having awakened the laryngologists to the possibilties of the extralaryngeal approach to the arytenoid cartilage. Since his papers in 1939,[1] with his report of an unusual number of successes by this method, no less than four new methods have been devised for the external approach to the arytenoid cartilage. This cartilage in the opinion of most surgeons is still the keystone in the success or failure of any operative procedure for the surgical relief of bilateral abductor paralysis of the larynx.

Hence, it seems proper and timely, after a period of seven years, to again review the literature on this subject and attempt to standardize the different surgical procedures advocated, so that laryngologists contemplating this work will have some facts to guide them in determining which type of surgical relief is best suited to their particular requirements.

This review is my own and I state the facts as I see them, as a laryngeal surgeon; it is not to be misconstrued as a criticism of any person or surgical technic. Few surgical technics are perfect. There is nearly always something to be desired.

THE KING OPERATION

With that idea in view, I shall consider first Dr. King's operation and see if it can be determined by examination of his original technic what led to the development of the arytenoidectomy procedure.

I believe some operators became discouraged with Dr. King's technic as originally described for several reasons: First, they found it difficult or almost impossible to distinguish or separate the anterior belly of the omohyoid muscle in those thyroidectomized patients

---

Read before the Section on Laryngology, Otology and Rhinology at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 3, 1946.

[2] Woodward, F.

who had undergone more than one operation, or whose pretracheal muscles had been cut in a single operation or in whom roentgen treatment followed thyroidectomy. The attempts of some surgeons to dissect the upper part of the anterior belly of this muscle resulted in difficult bleeding, which interfered with the remainder of the operation. Also, to the uninitiated surgeon, it was often a shock to cut into a neck on which several previous operations had been performed and to be confronted with a mass of fibrous and scar tissue in which he was unable to distinguish any muscular structures. Moreover, when it came to cutting, dissecting and elevating the inferior constrictor muscle and to exposing and separating the pharyngeal mucosa from the posterior surface of the cricoid cartilage and the alar of the thyroid cartilage, the presence of a large amount of fibrous and scar tissue caused some of them to perforate into the pharynx and left them pretty much disoriented.[3] Also, much stress was laid on the severance of the interarytenoid muscles in order to properly mobilize the arytenoid and allow its displacement without distorting the larynx and pulling the intralaryngeal structures to the side on which the operation had been performed. Some operators said in the reports sent to me that they failed to do this or, in cases in which it was done, it was not done completely enough to prevent the healing of the muscles and the pulling of the arytenoid back to the median line.

It was to overcome these difficulties which had been outlined to me by surgeons who had tried the King technic after reading Dr. King's paper of March 1939, that I devised the window operation for the complete extralaryngeal removal of the arytenoid cartilage. I first performed this operation on Nov. 3, 1939 and have continued to use it with some modification since that time.

ARYTENOIDECTOMY

My thought was, as originally stated, to get some more space in the larynx by removing the arytenoid by the simplest method I could devise and to let nature relieve the patient's distress by the formation of scar tissue. I later found that it was necessary, in order to insure uniformly good results, to place a suture through the cord and to fix it away from the median line of the larynx. This modification was also made by Dr. Edward Wright of Atlanta, Ga.[4]

It was not long after the publication of my technic[5] until surgeons began to complain about the arytenoidectomy operation. They were having difficulty working through a "keg hole," as one surgeon expressed it. Also they complained that since the larynx varied in size and shape the size and location of the window would have to be varied accordingly. They claimed that for this reason the technic was not constant, hence misleading; that it wasn't necessary to go through the tedious dissecting out of the arytenoid cartilage through a window and that just mobilizing and dislocating the arytenoid into the window was sufficient to give a good result. One surgeon cited three good reasons why the arytenoidectomy technic was no good and then in the next paragraph acknowledged that he had never attempted the operation on the living.

It was a desire to simplify the locating of the position at which to make the window in the thyroid cartilage that stimulated Drs. Julius W. McCall and Frederick S. Gardiner[6] of Cleveland to devise a method of transilluminating the larynx by use of a brightly lighted anterior commissure laryngoscope. After the arytenoid is located by the shadow it casts on the thyroid alar, the window is made. After the window is made by use of the laryngoscope, the arytenoid is fixed with a needle or skin clip intralaryngeally and the end of the suture is passed through the intralaryngeal mucosal membrane and out the window. This maneuver assists in delivering the arytenoid into the window after it is mobilized. The arytenoid is not removed but sewed into position in the window. Personally, I see no need for the transillumination and second, if you have the arytenoid delivered at the window, why not remove it? This procedure, I believe, was advocated by some laryngologists from Chicago who considered that it was better than placing a suture. These are personal modifications and in my opinion have no bearing on the general principles of the surgery involved.

In November 1943 Dr. Henry Orton[7] came forward with another technic to simplify the arytenoidectomy and advocated the removal of the posterior third of the thyroid alar in order to make a wider field in which to remove the arytenoid. His technic makes no effort to fix the cord away from the median line. It is true that this procedure does help to simplify the removal of the arytenoid cartilage; but my argument with him then and now is that one must preserve the continuity of the thyroid cartilage for consistently good results, because the soft tissues of the neck will fall into the larynx or be drawn to the median line after the surgical operation, particularly when the muscular tissue of the larynx is paralyzed.[8] I have tried it and I have seen it happen. Furthermore, the cord must be anchored to some fixed point in order to insure a good result.

Lately, Dr. DeGraaf Woodman[9] of New York, working on Dr. John Kernan's service at Presbyterian Medical Center, has come forward with a new technic, which is a combination of Dr. King's approach and the complete removal of the arytenoid with a fixation of the cord by putting a suture through the alar cartilage. He has gone so far as to advocate the severance of the lower thyrocricoid articulation, a procedure which in my opinion is unnecessary. It creates just that much more trauma and secondary edema to a paralyzed larynx and increases the necessity for a feeding tube.

He has also advocated elevation of the perichondrium on the mesial surface of the alae of the thyroid cartilage rather than just the elevation of the pharyngeal mucosa. This is undoubtedly an added precaution against rupture of this mucosa. I have tried the operative procedure, and in my opinion there was considerable traumatic edema and difficulty in swallowing, which required the patient to use a feeding tube for three or four days. I could not see that it was any improvement over Dr. King's approach or the arytenoidectomy technic. In older patients in whom the cartilage has undergone definite ossification, care should be exercised to traumatize the laryngeal box as little as possible.

[9] Woodman, DeG.: A Modification of the Extralaryngeal Approach to Arytenoidectomy for Bilateral Abductor Paralysis, Arch. Otolaryng. **43:** 63 (Jan.) 1946.

From the foregoing analysis one can sum up the situation in regard to bilateral abduction muscular paralysis by saying that there are two definite surgical procedures which have been tried and not found wanting according to the statistics of successful results up to the present time. There is the posterior approach of Dr. King with the attendant mobilization and fixation of the arytenoid cartilage to the alae of the thyroid cartilage. And the second procedure may be described as the arytenoidectomy in which a direct approach is made to the arytenoid cartilage through a window made in the thyroid cartilage with an effort to minimize as much as possible any trauma to the surrounding tissues and to procure more space in the larynx by taking out the arytenoid cartilage. When operating in a small, narrow larynx, it is an easy matter by this method to remove some of the muscle tissue of the cricoarytaenoideus or thyroarytaenoideus muscles, if more separation of the cords is desired. Both these surgical procedures it is known from past experience have given a good percentage of successful results; hence it is for the surgeon to decide which technic he prefers.

ABSTRACT OF DISCUSSION

Dr. Simon Jesberg, Los Angeles: This matter of bilateral abductor paralysis of the larynx appears to be something like a deviated septum of the nose. There is obstruction to the respiratory tract, and one is trying to find some way to get a passage through. This distressing condition probably does not bother the patient as much as it does other people when the patient makes this terrible noise at night. Whether the arytenoid muscle is displaced or removed does not make a great deal of difference. One might as well come back and say that in a nose there is an obstruction with a deviated cartilage. Shall it be removed or displaced? Personally, I would remove the cartilage. Brien King, in his original work, thought that the omohyoid would cause motility of the arytenoid. This, however, is not true. His implantation did not bring about movements of the vocal cords during respiration. One has either to remove or displace the arytenoid. Room has to be made in there, just as it does in the nose if one is going to get rid of obstructive cartilage.

Dr. Lewis F. Morrison, San Francisco: I am sorry that Dr. Kelly ran out of time. I should like to have had him go on a little further. He had one or two things that I might like to take him on with, maybe for one or two rounds. It would be interesting, I think, mostly to us, not to a great many of the rest. There is one point I should like to mention which was brought to my attention by Dr. Brien King when he first came to the university to tell what to do with this condition. He had had some extremely unpleasant news from the eastern section that the procedure had been tried by several good laryngologists and that the results were almost universally poor. In fact, they were failures. He told me, "If you learn your anatomy, don't expect to find it there when you go for it, because this is not virgin territory that you are going to get into, but it is very nice to know what ought to be there." So I spent a great deal of time on fresh cadaver material and then started out with the King procedure, mostly as it was outlined. I am grateful to Dr. King for encouraging me to learn my anatomy from the outside. As a result of that, in getting into these second, third and fourth operative fields, one does not feel quite as unhappy about the scar tissue. If one takes a little time, the bleeding can be controlled adequately. Once one has gotten to the inferior constrictor muscle, from then on the going is usually undeterred by scarring, possibly with one exception. I entered into virgin territory in a person who had a diffuse, disseminated arthritis and whose joints were arthritic; I had a difficult time finding the cricoarytenoid joint.

Dr. Brien T. King, Seattle: Dr. Kelly has mentioned the difficulties and bleeding encountered while performing the operation for bilateral cord paralysis by the technic described by me. Only two vessels of any importance are encountered. The first is the superior thyroid artery. I have found it necessary to ligate that artery in only about 20 of 79 operations for bilateral cord paralysis, and there is little difficulty in its ligation. The vessel that almost invariably gives me trouble, but only of the nuisance sort, is a branch of the superior laryngeal artery, which runs down the very bottom of the pyriform fossa and anastomoses on the posterior surface of the cricoid cartilage with the corresponding vessel on the opposite side. I have found it extremely difficult to ligate that vessel, but bleeding is easily controlled with electrocoagulation. I no longer consider the omohyoid muscle of importance in the operation. I still attach it to the arytenoid cartilage. Dr. Morrison does not, and his results are as good as mine. It is my opinion that the retention of the arytenoid cartilage is an important consideration in the operation. I think Dr. Kelly goes about his operation in the hard way. He is performing an important operation through a window in the thyroid cartilage which is ⅜ inch (1 cm.) in diameter. Dr. Woodman of New York has recently described a modification of Dr. Kelly's technic which to me is simpler and offers 1½ inches (4 cm.) exposure of the posterior surface of the larynx in which one can easily visualize the subsequent steps of the operation. It is the same approach which I use, except that I prefer to outwardly rotate and displace the arytenoid cartilage rather than to excise it. The fibers of the inferior constrictor of the pharynx along the lateral border of the thyroid cartilage are divided. It is then necessary to carefully remove or dissect the pharyngeal mucosal attachments from the posterior border of the thyroid cartilage. When that is accomplished the mucosa can easily be pushed out of the pyriform fossa and off the posterior surface of the cricoid cartilage. This will give the operator a good view of the region in which the important technical details of the surgical procedure are to be carried out. Experience has taught me that a separation of the posterior ends of the vocal cords of from 4 to 5 mm. gives the best results. More than 6 mm. will give only a whisper for a voice. Three millimeters or less, will produce an inadequate airway.

Dr. Lorenz Ruddy, Sacramento, Calif.: We are indeed fortunate in having at this meeting the three main contributors to this subject, Drs. King, Kelly and Morrison. It is with a humble attitude that the following comments are offered from a more limited experience: 1. The cosmetic benefits of horizontal incisions should be stressed. 2. The window approach is personally preferred because it is more direct. It exposes the vocal process of the arytenoid at one end of the operative field and its muscular process at the other. 3. To overcome some of the difficulties, the following technic was devised and used with success: a. The window is made at least ½ inch (1.3 cm.) square, leaving a posterior and inferior cartilage rim ⅛ inch (0.3 cm.) wide. b. After locating the arytenoid by probe and dissecting the muscle from its lateral face, the displaced muscle oved by scissors. The remaining steps can then be taken pered by redundant tissue. c. The King operation has strated that arytenoidectomy is not necessary for a sful result. The interarytenoid muscles, however, must be from their action on the arytenoid. This can be accom- d by severing the cricoarytenoid joint capsule, displacing ytenoid and dissecting away its interarytenoid muscle and a on its posterior surface as far as its medial border. reed superfluous muscular process is then removed. The and vertical processes of the arytenoid, however, are left ce. Dissecting them free of the mucosa on their medial e is tricky, liable to perforation and undesirable. It is vantage to leave the mucosa attached, for in pulling the ning portion of the arytenoid cartilage laterally for fixa- this mucosa is brought with it. d. Finally, a fine chromic e is passed through the tendinous portion of the posterior f the cord, the importance of which has been stressed by s. Another is passed around the center of the vertical ss of the arytenoid. The two sutures when retracted lly can provide the space desired, as determined by goscopic examination. It is important to fix these sutures at their lateral pull is along the same horizontal plane in the vocal cord is normally situated; if this is not done, oice may be unnecessarily altered. The frame of the thyroid ow provides fixation for the sutures in the position that is ed.

. JOSEPH D. KELLY, New York: I am sorry I could not this paper, whose whole object was to develop the reasons and the difficulties experienced with, not only the King tion but arytenoidectomy and all the other procedures that o the development of the things that followed. The object not to criticize the technic of the King operation as it is cted today but rather to give a historical development of easons why the surgical technic in the beginning was faulty these other technics were devised as improvements. I ed to present them in such a way that their successes and es might be known and the surgeon could decide what of technic he could use best. The only argument that King and I have ever had about the treatment of this tion has been whether or not the best results are obtained aving the arytenoid cartilage in or taking it out. At present eve both of us have handled a sufficient number of cases to ardize the operative procedures we have advocated, and depends on the surgeon's particular manual dexterity ner or not he prefers the arytenoidectomy operation or, as King says, the posterior approach.

---

ne of the Greatest Miracles of Modern Medicine.—ly I would like to speak of the miracle which has occurred iminating tetanus from military surgery. Let me recall figures: In our Civil War the mortality rate was from 95 per cent. Shortly before World War I under the it of antitoxin, which was discovered and elaborated on by se of animals, the mortality rate had dropped to between nd 80 per cent. During World War I large statistical nce showed a mortality rate of 20 to 58 per cent, but in the nd World War only 11 cases are known to have occurred g 10,700,000 men. Of these 11 cases, 5 had been given d and 6 had not. Moreover, in the 11 cases there are ds of only 4 deaths, 2 of which occurred in individuals who received the basic series of toxoid but no booster dose, and individuals who had not received even the basic series. is, in my mind, one of the greatest miracles of modern cine. The basis of the establishment of a proper toxoid squarely on animal investigation, and no greater debt could knowledged to our friends in the animal kingdom than this nce for the good of humanity.—Cutler, Elliott C.: Experi- of an Army Doctor in the European Theater of War, *J. Surg.*, June 1947.

NEBULIZATION THERAPY IN BRONCHIECTASIS

The Use of Penicillin and Streptomycin Aerosols

ARTHUR M. OLSEN, M.D.
Rochester, Minn.

Aerosols have been employed at the Mayo Clinic in the treatment of secondary infection associated with bronchiectasis since August 1944. A preliminary report of experience with penicillin aerosol therapy was made in June 1945.[1] Particular reference was made to the use of the method in the preparation of patients with bronchiectasis for pulmonary resection. In February 1946 the use of nebulized streptomycin was reported briefly.[2]

At the present writing, nebulization therapy has been used at the clinic for 86 patients with chronic bronchiectasis. Forty-six of these patients were treated in preparation for surgical resection of portions of the lung. The remaining 40 patients had bilateral bronchiectasis or were not suitable candidates for surgical intervention. In these 40 cases aerosol therapy was instituted in the hope of reducing the volume of pulmonary secretions. In all 86 cases aerosol penicillin was used. However, in 27 cases streptomycin hydrochloride [3] was added to the penicillin solution for nebulization.

SUMMARY OF THE LITERATURE

Contributions to the study of aerosol therapy have been reviewed thoroughly by Segal [4] in a recent article. Many substances have been used for inhalation therapy including solutions of sulfonamide compounds.[5] Bryson, Sansome and Laskin [6] were the first to demonstrate a method for nebulization of penicillin solutions, and they showed that penicillin was absorbed from the lungs and excreted in the urine. Much of the fundamental investigation in the field of inhalation therapy has been done by Barach. Barach and his associates [7] published their preliminary observations on treatment with penicillin aerosol in April 1945. Significant contributions in methods of administering penicillin aerosol have been made by Mutch and Rewell,[8] Knott and Clark [9] and Hagens and his associates.[10] Segal and Ryder [11] have reported the application of penicillin by inhalation to the treatment of acute and serious forms

of respiratory disease Bobrowitz and his associates[12] used both inhalation and tracheal instillation in treating the infection associated with bronchiectasis in 12 cases Barach and his associates[13] applied the method to the treatment of disease of the accessory nasal sinuses. Nebulized penicillin has been used in a variety of conditions by Vermilye[14] and also by Hanks[15] The results obtained by Vermilye and by Hanks in the treatment of bronchial asthma have not been secured by other investigators.[11] Aerosol treatment for a variety of constitutional symptoms presumably related to the bacterial flora of the upper part of the respiratory tract does not seem to be justified at present.

METHOD OF ADMINISTRATION

The method of administration employed was as follows: A glass nebulizer[16] was connected by means of rubber tubing to an oxygen tank equipped with a reducing valve and flow meter (fig 1). The solution was placed in the nebulizer, and the passage of 4 to 6 liters of oxygen through the nebulizer produced a fine mist. The patient held the open end of the nebulizer in his mouth. A Y tube was inserted into the tubing between the reducing valve and the nebulizer. During inspiration the patient closed the Y tube. The Y tube remained open during expiration, and oxygen escaped. Thus, oxygen passed through the nebulizer only during the inspiratory phase of respiration, and loss of the drug was reduced to the minimum. If the breath was held for a few seconds after each inhalation, a greater amount of the therapeutic agent was retained in the bronchial tree. The pressure necessary to nebulize solutions in the nebulizer can be supplied by a small motor and air compressor as well as by the oxygen tank. In consideration of the results obtained in this series the possible therapeutic benefit of oxygen therapy should not be discounted entirely; however, for practical purposes any source of air pressure should be adequate. Air pressure has proved to be satisfactory for treatment by nebulization in the home.

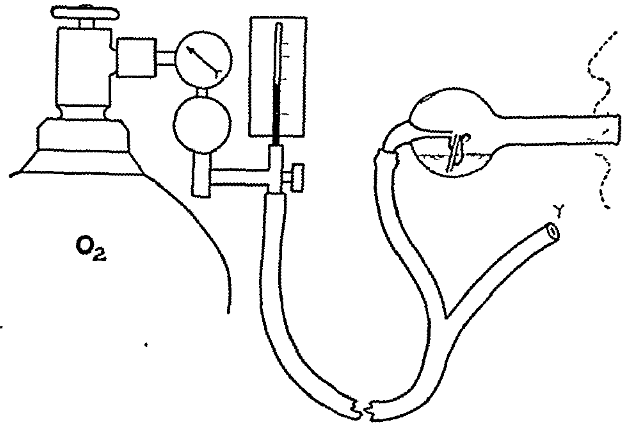

Fig 1 —Apparatus used for nebulization therapy Oxygen used as source of positive pressure, 4 to 6 liters per minute required Y tube is closed during inhalation, opened during exhalation "Vaponefrin" type of nebulizer is illustrated

Modifications of the standard glass nebulizer have been devised to prevent loss of too much of the drug during expiration.[7] A special nebulizer with a large bulb may be used, or a collapsible rubber rebreathing bag may be attached to a standard nebulizer. Such modifications have been helpful for children and older persons who have found it difficult to close the Y tube during inspiration and to open it during expiration. An automatic demand type of oxygen regulator also has been devised to deliver oxygen pressure only during inspiration.[17] The patients treated at the clinic whose general health has been good usually have preferred the standard nebulizer because it is easy to handle. For special cases an oronasal mask has been attached to the nebulizer.

At the clinic, the sodium salt of penicillin dissolved in isotonic solution of sodium chloride has been used most frequently for nebulization. A standard solution of 10,000 units per cubic centimeter has been employed routinely for hospital practice. Streptomycin hydrochloride likewise was dissolved in saline solution and was used in concentrations of 25 to 50 mg (25,000 to 50,000 streptomycin units) per cubic centimeter. Solutions of penicillin or streptomycin can be nebulized at the approximate rate of 1 cc. every ten minutes Periods of rest were advisable, and most patients planned to nebulize 3 cc. each hour. During the course of a day patients nebulized from 20 to 30 cc. without difficulty, and the period of daily treatment usually lasted ten hours. The rather prolonged period of treatment has been used because it has been demonstrated that the bactericidal effect of penicillin requires a constant exposure of the bacteria to the drug for four to six hours[18]

Penicillin sodium and streptomycin hydrochloride were combined in solution for aerosol therapy. Two hundred thousand units of penicillin and 0 5 Gm. (500,000 streptomycin units) or 1 Gm. (1,000,000 streptomycin units) of streptomycin were mixed in 20 to 30 cc. of isotonic sodium chloride solution. In vitro studies conducted by F. R. Heilman[19] have demonstrated that combining these drugs does not impair the antibacterial activity of penicillin. Streptomycin is quite stable in this solution. In nearly all instances in which nebulized streptomycin has been used at the clinic, it has been combined with penicillin sodium.

All the patients who had bronchiectasis were hospitalized for aerosol therapy. Postural drainage was instituted in each case, and a careful record was kept of the daily volume of the sputum as well as its character, consistency and odor. Bronchoscopic examination was carried out in all cases, and complete bronchographic studies were made. Secretions were aspirated at the time of bronchoscopic examination for bacteriologic study. During treatment specimens of sputum were obtained at frequent intervals for bacteriologic study.

RESULTS OF TREATMENT

Surgical Cases.—Nebulization of an antibiotic agent was employed as a preoperative measure in 46 cases. Surgical procedures carried out in these cases by Harrington, Clagett and Gray included resection of the lower lobe of the left lung in 19 cases; of the lower lobe and

lingula of the upper lobe of the left lung in 11; of the lower lobe of the right lung in 6; of the lower and middle lobe of the right lung in 3; pneumonectomy in 6 and segmental resection of the superior portion of the lower lobe of the right lung in 1 case. In 7 of the cases in which a single lobe was removed, some degree of bronchiectasis had been demonstrated in other lobes. Bronchoscopic aspiration was performed in all cases after pulmonary resection while the patient was still on the operating table.

Penicillin aerosol therapy was administered to all these patients for periods varying from four days to four weeks before operation. Some of these patients received penicillin by the intramuscular route for from twenty-four to forty-eight hours prior to operation, and all 46 received penicillin by the intramuscular route for varying periods after operation. In 7 instances in which pulmonary secretions revealed gram-negative bacteria, streptomycin and penicillin were mixed for aerosol therapy before operation.

In the majority of the surgical cases the volume of pulmonary secretions was reduced considerably in the preoperative period. The routine postoperative bronchoscopic examination often revealed that the bronchial tree was practically free of secretions. When preoperative nebulization therapy had been effective, additional bronchoscopic aspirations for the relief of pulmonary atelectasis have been required only infrequently. In 10 of the 46 cases, postoperative atelectasis occurred and bronchoscopic aspirations were performed. Nine of these 10 patients had not responded well to treatment with nebulized penicillin, and 4 of the 10 were children. Empyema which required external drainage developed after operation in 4 cases. Three of these patients had not experienced a satisfactory reduction in the quantity of sputum prior to operation. In general, an unsatisfactory response to treatment with penicillin aerosol could be correlated with the presence of gram-negative bacteria in the sputum. Only 1 patient treated with penicillin and streptomycin aerosols had any difficulty after operation. No postoperative fatalities occurred in this series.

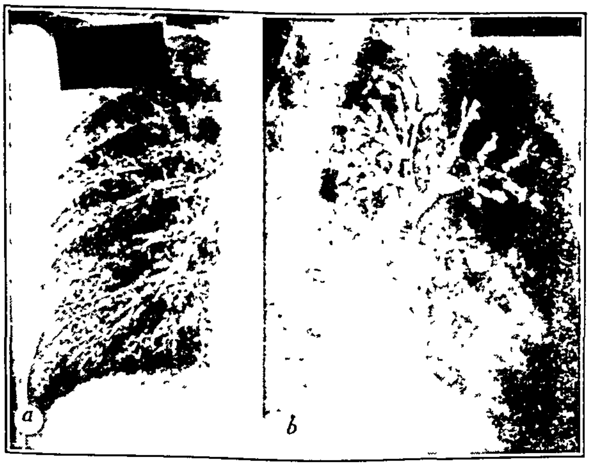

Fig. 2.—Bronchogram of woman aged 22 showing *a*, normal right lung; *b*, extensive bronchiectasis of the left lung Penicillin aerosol was given for seven days before operation. The volume of sputum was reduced from 150 to 30 cc per day. A pneumonectomy was performed, and no complications developed.

It is recognized that penicillin administered parenterally is valuable in the preparation of patients for thoracic surgery. White and his associates[20] have shown that penicillin given intramuscularly is effective in the prevention of postoperative empyema and other complications. The parenteral administration of penicillin to patients after operative intervention has undoubtedly contributed to the favorable postoperative course. However, it is my impression that nebulization therapy has been particularly efficacious in reducing the volume of pulmonary secretions prior to operation. Nebulization therapy was especially helpful in the 7 cases in which lobectomy was performed in the presence of bronchiectasis elsewhere in the bronchial tree. Adequate nebulization therapy may extend the indications for pulmonary resection in bronchiectasis (figs. 2 and 3).

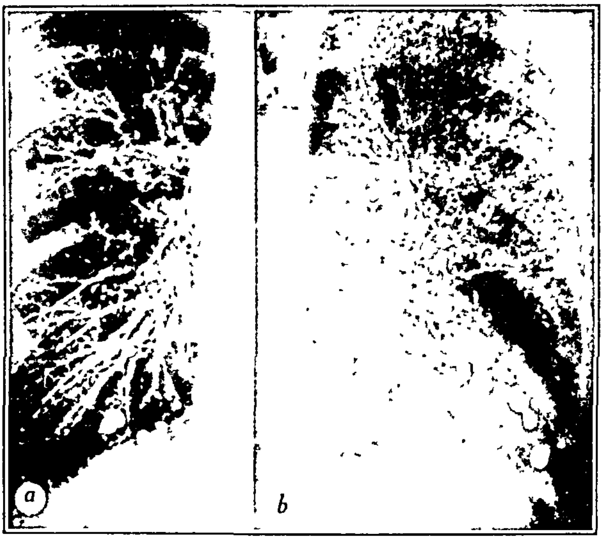

Fig. 3.—Bronchogram of woman aged 21 showing: *a*, saccular bronchiectasis of the lower lobe of the right lung; *b*, extensive saccular bronchiectasis of the lower lobe of the left lung. Penicillin aerosol was administered for twenty six days before operation. The volume of sputum was reduced from 240 to 45 cc. per day. Excision of the lower lobe of the left lung was performed without complications. The patient has continued aerosol therapy.

Nonsurgical Cases.—Forty patients who had bilateral bronchiectasis have been treated by the method of nebulization. Conventional methods of therapy, such as postural drainage, climatic change and bronchoscopic aspirations, had been tried by many of these patients without much benefit. Several of the group had been treated previously with sulfonamide compounds and parenterally administered penicillin with little or no improvement. The age of these patients ranged from 8 to 70 years.

All 40 patients were treated in the hospital for periods of two to eight weeks. The average duration of the stay in the hospital was four weeks. The long period of treatment allowed an opportunity for complete study. Although adequate investigation of the levels of penicillin in the blood and determinations of urinary excretion of penicillin had been made by other workers[21] using similar methods of administration, determinations were carried out for some of these patients to make certain that penicillin was being absorbed and excreted. In general, patients excreted from 10 to 20 per cent of the inhaled penicillin in twenty-four hours. Streptomycin could be demonstrated in the urine in small quantities after inhalation of this drug.

[21] Bryson, Sansome and Laskin.[6] Barach, Silberstein, Oppenheimer, Hunter and Soroka.[7] Segal and Ryder.[11]

All 40 patients were treated with nebulized penicillin first, and 20 of the 40 patients were treated with aerosol penicillin only. In recent months, however, a limited quantity of streptomycin hydrochloride has been available for aerosol therapy of those patients whose pulmonary secretions contained gram-negative bacilli. The other 20 patients, therefore, were treated with a combination of penicillin and streptomycin aerosols.

Results of nebulization therapy were considered satisfactory if the daily volume of purulent secretions was reduced 75 per cent or more. In 19 of the 40 cases penicillin aerosol did not reduce the daily volume of sputum to a fourth of its previous volume. In 21 instances satisfactory reduction in volume of sputum was obtained.

Streptomycin hydrochloride was used in combination with penicillin for 6 of the patients (cases 1 to 6) who had responded satisfactorily to penicillin aerosol alone (table 1). Gram-negative organisms had been demonstrated in the sputum of these 6 patients. Further reduction in sputum was obtained from this treatment in each of these 6 cases, and some of these patients became almost free of cough, at least temporarily. An example of this group is shown in figure 4 (case 6, table 1).

The combination of streptomycin and penicillin aerosols was used also for 14 patients who had not responded satisfactorily to penicillin aerosol alone and who had gram-negative bacilli in the sputum. Twelve of these 14 patients obtained a good result by nebulizing the combined solutions. The bronchogram of 1 of these patients is shown in figure 5 (case 9, table 1). This treatment did not reduce by three fourths the volume of sputum of 2 patients. One of these was an elderly man (case 20) who had pulmonary fibrosis and emphysema superimposed on brochiectasis. The other failure occurred in a young man (case 19) who had situs inversus and bronchiectasis. His pulmonary secretions were reduced only 50 per cent after thirteen days of treatment by nebulization.

Thus, with penicillin aerosol alone slightly more than half of the patients treated obtained a 75 per cent reduction in volume of sputum. Of the 20 patients treated with combined penicillin and streptomycin aerosols, 18 obtained a satisfactory result. Admittedly, several of these patients might have done better than they did with penicillin alone if it had been used for a longer period. There were 7 failures in the group of 40 nonsurgical cases. In 2 of these cases penicillin alone and the mixture of penicillin and streptomycin both failed to elicit a good response. The other 5 patients whose response was unsatisfactory never had the opportunity to use nebulized streptomycin. In most instances failure to respond to penicillin aerosol therapy was due to the predominance of gram-negative bacteria in the sputum. However, the ability of the patient to cooperate is an important factor. The very young and the very old do not do well. The presence of emphysema and pulmonary fibrosis associated with bronchiectasis militates against successful treatment. In these patients the mixing of tidal air with residual air has been shown by physiologic measurements to be defective. The drug does not reach the diseased area in effective concentrations.

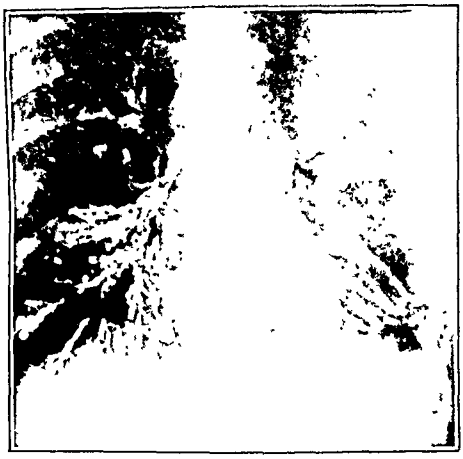

Fig. 4 (case 6, table 1).—Bronchogram of woman aged 37, revealing bilateral bronchiectasis. Penicillin aerosol therapy was used for twenty-six days, with supraglottic instillation of penicillin in addition for the last ten days. The amount of sputum was reduced from 120 to 25 cc. per day. The patient gained 10 pounds (4.5 Kg.) Subsequently streptomycin and penicillin aerosols were administered because Escherichia coli and Hemophilus influenzae were demonstrated in the sputum. The volume of sputum was reduced to practically nothing. The patient has continued treatment at home.

Reactions to either penicillin or streptomycin were uncommon when these drugs were nebulized. When penicillin aerosol was used, urticaria developed in 3 cases and a mild arthralgia in 2. It was found that these symptoms could be controlled by the oral administration of diphenhydramine hydrochloride ("benadryl hydrochloride" N. N. R.). Three patients complained of a sore tongue after several days of nebulization. In several instances a sharp rise in temperature and a chill were noted after administration of streptomycin by inhalations. In most instances this could be attributed to the particular lot of streptomycin used, which was not of standard purity and was not suitable for parenteral administration. Treatment could be continued with a different lot of the drug.

SUPRAGLOTTIC INSTILLATION OF PENICILLIN AND STREPTOMYCIN

The instillation of chemotherapeutic substances into the bronchial tree has been used for several years. Vinson [22] reported on the bronchoscopic insufflation of sulfonamide preparations, and Tucker and Atkins [23] have used similar methods of treatment. May and Floyer [24] and Kay and Meade [25] have treated pulmonary suppuration by instilling penicillin. Romansky and his associates [26] mixed penicillin with iodized oil for instillation into the bronchial tree in cases of bronchiectasis.

Penicillin, streptomycin or combinations of these in solution can be instilled into the trachea in much the same manner that iodized oil is instilled for diagnostic purposes. One hundred and sixty-five instillations have been made in 15 cases at the clinic. Fifty-two of these instillations were made in 3 cases of chronic bronchiectasis, in which nebulization therapy was not used. Two of these 3 patients thought that they were helped by this treatment. One hundred and thirteen instillations were given to 12 patients who were carrying out nebulization therapy. Although results are difficult to evaluate, it is my impression that the direct intratracheal administration of penicillin and streptomycin is a valuable adjunct to nebulization therapy, as illustrated by case 6 of table 1 and in figure 4.

For supraglottic instillation 100,000 units of penicillin sodium in 10 cc. of isotonic solution of sodium chloride and 0.5 Gm. (500,000 streptomycin units) of streptomycin in 5 cc. of the same type of solution were used. Patients can tolerate 10 to 15 cc. of solution at a single daily treatment. Preliminary cocainization of the throat is usually necessary. The material should be instilled slowly. Obviously, some patients are able to cooperate more satisfactorily than others for this treatment.

BACTERIOLOGY OF PULMONARY SECRETIONS

The work on nebulization therapy has stimulated interest in the bacteriologic aspect of pulmonary secretions. I am indebted to Drs. F. R. Heilman and Luther Thompson of the Section on Bacteriology at the clinic, who have carried out hundreds of detailed bacteriologic examinations on sputum. Material was aspirated at the time of bronchoscopic examination, and further specimens of sputum were obtained at regular intervals during the course of nebulization therapy. In many

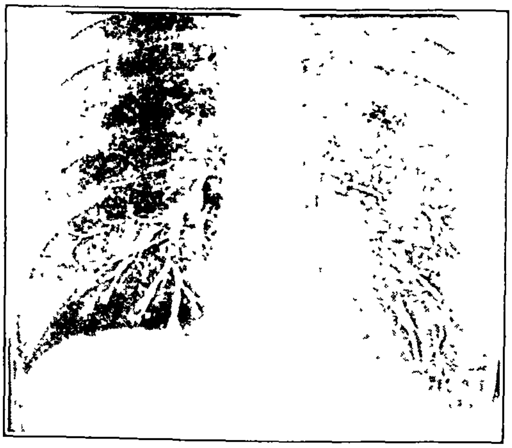

Fig. 5 (case 9, table 1).—Bronchogram of woman aged 27, revealing bilateral bronchiectasis. Treatment with penicillin aerosol for nine days gave little benefit. Aerobacter aerogenes and H. influenzae were demonstrated in the sputum. Streptomycin and penicillin aerosols were given for twenty-one days. The volume of sputum was reduced from 175 to 20 cc. per day and cultures were negative at the conclusion of treatment.

instances in vitro studies have been made to determine the sensitivity of a particular organism to penicillin or streptomycin. Drug resistant bacteria or strains have been encountered.

Smears and cultures of pulmonary secretions were likely to reveal many different types of bacteria in the same patient. After penicillin therapy, gram-positive organisms usually disappeared and gram-negative bacilli often were recognized that could not be identified on the original smears. The types of bacteria and the frequency of occurrence in this series of 86 cases are given in table 2. Neisseria catarrhalis was not included in the list in table 2, as it appears to be a nonpathogenic organism which is present in nearly all sputum. Green-producing streptococci are included in table 2, although their significance is questioned. Adequate bacteriologic studies of pulmonary secretions should be carried out in all cases of pulmonary suppuration in which nebulization therapy is to be undertaken.

COMMENT

New methods of treatment in bronchiectasis should be regarded with a critical attitude. When possible, surgical resection of the affected portion of the bronchial tree is the best treatment. Treatment by nebulization of an antibiotic agent appears to be helpful in the preparation of patients for lobectomy. Reduction of the volume of pulmonary secretions and eradication of many bacterial organisms make surgical resection of one or more lobes of the lung an easier and safer procedure. The use of antibiotic preparations by both the aerosol and parenteral methods of administration should greatly reduce the mortality and morbidity from pulmonary resection for suppurative disease of the lung.

M albicans	12

When nonsurgical or bilateral bronchiectasis is treated by nebulization therapy, it must be borne in mind that the secondary infection is being treated rather than the primary disease. There is no reason to believe that ectatic bronchi will be restored to normal. Furthermore, it must be borne in mind that the relief of bronchorrhea obtained by nebulization therapy is likely to be temporary. Several of the patients in this series have reported partial or complete recurrence of symptoms following cessation of therapy. Most of the patients have continued to use aerosol penicillin in their own homes after leaving the hospital. It is apparent that the great majority of patients must continue nebulization on an intermittent or modified program if they are to maintain their improvement. Furthermore, it is likely that many bacteria in the bronchial secretions of patients who have bronchiectasis will become resistant to antibiotic preparations, especially streptomycin, as aerosol treatment is continued for long periods. The development of drug-fast bacteria is one of the most serious problems confronting investigators in the field of antibiotic therapy. Nevertheless, patients who suffer from the physical disabilities and social disadvantages of chronic suppurative bronchiectasis are eager to try any treatment which offers them partial relief. Inhalation therapy with penicillin and streptomycin aerosols has proved to be helpful in suppressing the secondary infection which complicates bronchiectasis.

ABSTRACT OF DISCUSSION

Dr. Alvan L Barach, New York: Dr. Olsen's interesting presentation illustrates in a conclusive way that there are certain cases of bronchiectasis in which the combined administration of penicillin and streptomycin aerosols results in prompter and more pronounced improvement than does penicillin alone. Over half of the patients treated with penicillin aerosol alone responded favorably, whereas 18 of 20 cases in his series showed unmistakable benefit with both penicillin and streptomycin aerosols. I should like to discuss the significance of gram-negative organisms in the sputum in these cases. Observations have been made on about 200 cases of bronchopulmonary disease treated with penicillin It is a consistent observation that gram-negative organisms, Escherichia coli or coliform organisms, Bacillus pyocyaneus and Aerobacter aerogenes, appear after one or two weeks of treatment. These organisms frequently continue in the sputum in predominant culture, whether improvement has taken place or has not It appears from the work of Abraham and Chain that many of these organisms, which may be of themselves nonpathogenic, elaborate an enzyme, penicillinase, which inhibits the bacteriostatic activity of penicillin. It is my impression that the favorable results obtained by Dr. Olsen when streptomycin was added to penicillin may be traced to this disappearance of gram-negative organisms and, therefore, to the absence of the enzyme penicillinase. Experience has shown that patients with bronchiectasis may not improve for one or two weeks, even with combined intramuscular injection of penicillin and penicillin aerosol, but that in three to five weeks definite improvement may take place The problem of chronic disease must be studied from a different point of view than that from which acute infection is treated. Chronic swelling of the mucous membrane may take a long time to disappear. It will require a good deal more time before it is possible to determine the significance of gram-negative organisms and how they may best be treated My belief is that whereas streptomycin results in a prompt improvement in a far larger proportion of cases, perhaps somewhat larger doses of penicillin over somewhat longer periods of time may result in clinical improvement in severe cases of bronchiectasis and in improvement sufficient to make these people who are semi-invalids capable of carrying on a reasonably active life without purulent sputum and the danger of progressive infection.

Dr. Maurice S. Segal, Boston: I am in agreement with Olsen's observations and have found penicillin aerosols effective in a series of 42 patients with chronic bronchiectasis. Eight patients with bronchiectasis subsequently underwent surgical intervention, and there were no postoperative complications. Fourteen were considered unsuitable for surgical intervention because of multiple lobular involvement. Temporary clinical improvement was observed in this group. Recurrence of symptoms, however, appeared in most of these cases within one to six months Twenty patients with involvement of one or two lobes, mostly lingular, were considered ideal for purely medical observation Definite clinical improvement was observed in 14 of these patients. Many had previously received courses of parenteral penicillin and oral sulfonamide drugs without appreciable improvement. Remissions for as long as a year and a half were observed in 2 patients of this group There was no recurrence of pneumonitis in 6 of this group for a period up to five months I consider the minimum course of treatment six weeks and repeat therapy, in this latter group particularly, at intervals of three months for at least one year. Seven patients with chronic sinusitis complicated by bronchiectasis have been treated. They responded well to aerosol therapy directed via the nasal and pulmonary route while in the hospital, but in almost all these cases the infection returned to the sinuses within several weeks of therapy. Intermittent negative suction and pressure therapy, as described by Dr. Barach, were not employed. Streptomycin aerosol was employed for the management of gram-negative Friedländer organisms in 2 patients with bronchiectasis. With repeated use of streptomycin, there was observed the rapid development of resistive strains which could not be eradicated despite tremendous doses. I have not observed the appearance of penicillin-resistive strains in patients treated with penicillin aerosol. I have found the occasional intrabronchial instillation of penicillin alone or with streptomycin following bronchoscopic aspiration of considerable help in combating the more serious types of infection associated with extensive suppurative disease. I and my associates are also attempting to combine therapeutic agents with penicillin aerosol to delay its absorption through the pulmonary tree. Preliminary studies suggest that "neosynephrine" (N. N. R.) may be employed to achieve greater topical efficacy and less systemic effect.

Dr. A. M. Olsen, Rochester, Minn.: I wish to thank Dr. Barach and Dr. Segal for their kindness in discussing my paper. I do think that inhalation therapy has a definite place in the treatment of respiratory disease. I do not consider that at present inhalation therapy, particularly with the use of antibiotics, should be the method employed in systemic diseases that have no relationship to the respiratory tract. I was interested in Dr. Barach's possible explanation of the effect of streptomycin on gram-negative bacteria: the suggestion that these gram-negative bacteria may have a "penicillinase" which prevents the penicillin from acting effectively.

Clinical Notes, Suggestions and New Instruments

CHRONIC ERYSIPELOID (SWINE ERYSIPELAS) IN A MAN

The Effect of Treatment with Penicillin

GEORGE W. STILES, M.D., Ph.D.
Denver

Disease transmission from the lower animals to man is being recognized by the medical profession as of increasing importance in the control of many infectious maladies. One of these problems is swine erysipelas (erysipeloid in man) usually acquired by contact with diseased animals or their infected products.

The publications of Ehrlich,[1] Klauder,[2] Van Es [3] and others illustrate the hazard in dealing with infected animals on the farm or in the public abattoir, the laboratory, the fish market or the button factory.

During recent years the Denver Branch Pathological Laboratory of the United States Bureau of Animal Industry has diagnosed upward of 1,000 positive cases of erysipelas in swine, including a few arthritic lambs and diseased turkeys.[4] The diagnosis of these animals was made by serologic tests and the isolation of the swine erysipelas organism in most instances. The research on animals was made jointly by C. L. Davis, D.V.M., bureau pathologist, and me.

Samples of blood from 170 human subjects were tested for possible erysipeloid infection. Some of these specimens were furnished by the Colorado State Board of Health, to which they had been submitted for Wassermann tests; others came from the University of Colorado School of Medicine, and the remainder I drew from persons giving a history and showing symptoms or lesions of possible erysipeloid. Of this number, 30, or 17.5 per cent, gave positive reactions with swine erysipelas antigen in titers of 1:50 and upward. Four specimens gave reactions in a titer of 1:25 only and were considered suspicious. A reaction in a dilution of 1:50 was suggestive of probable infection with Erysipelothrix rhusiopathiae.

The serums from reacting human subjects came from persons largely engaged in meat-packing establishments or from livestock owners who had handled diseased swine. Suspicious or nonreacting samples were from persons whose history did not indicate active infection due to erysipelothrix.

Serums from 3 of the positive cases were submitted by Dr. J. V. Klauder of Philadelphia, and 10 of his 13 specimens proved negative in titers of 1:50. The history of 8 of these negative reactors suggested possible early cases of erysipeloid clinically, before the development of antibodies, whereas the cases of the 3 positive reactors were definitely diagnosed clinically as erysipeloid. Two of Klauder's 10 serologically negative cases were reported as clinically negative.

A specimen of human serum from a young soldier in a local hospital was classified as that of a patient with scarlet fever. The complete history in this case is unavailable. The reaction of the serum was positive in dilutions up to 1:1,000 with swine erysipelas antigen, and the reaction of the serum is still positive after it has been held in the refrigerator for over two years. The urticarial form of chronic swine erysipelas closely resembles the rash seen in human scarlet fever.

It is possible that this serum test would be of diagnostic value in the case of human beings with chronic arthritis of unknown cause, especially if the previous history indicated contact with diseased swine or other related occupational hazards. The symptoms of chronic arthritis of swine are not unlike symptoms of this disease observed in man.

As a result of the experience gained in testing both human and animal serums, I believe that the agglutination test offers a valuable aid in establishing a probable diagnosis of erysipeloid, perhaps of equal importance with similar reactions of the blood in typhoid fever and brucellosis.

This paper is presented because of the long duration period of infection apparently due to erysipelothrix in a man; the report is based on the history, clinical symptoms and a positive serologic reaction obtained with swine erysipelas antigen.

REPORT OF CASE

History.—J. M. was a man aged 27 at the time of infection, whose usual weight was from 185 to 190 pounds (84 to 86 Kg.). He was born on a ranch near Falls City, Neb. His previous history revealed the usual diseases of childhood without serious complications. On the death of his father (1919) the management of the farm passed to two brothers, the patient herein concerned and his elder brother, now a practicing veterinarian in that vicinity. Among other livestock raised on this farm were many swine, and during some years as many as four hundred head were raised on the premises. The herd was protected against hog cholera (a virus disease) by annual vaccination, but many swine died from other causes.

The symptoms, lesions involving the skin (either urticaria or sloughing backs) and arthritis, as well as hog specimens submitted to an animal biologic laboratory at Lincoln, Neb., proved that some losses were doubtless due to swine erysipelas. Through personal correspondence it was determined that E. rhusiopathiae had been recovered from hog specimens from this ranch, which had been submitted for examination by the brother who was a veterinarian. Swine erysipelas is known to be widely prevalent among hogs in Nebraska and in many other swine-producing areas.

It was a common practice for the farmer patient to handle acutely sick or chronically infected hogs and at the time of slaughtering his own hogs to reject an occasional animal for food because of its apparent illness. The initial infection of the thumb reported in this case was acquired under the aforementioned circumstances.

Bacteriologist in charge of the Branch Laboratory, Pathological Division, Bureau of Animal Industry, United States Department of Agriculture.

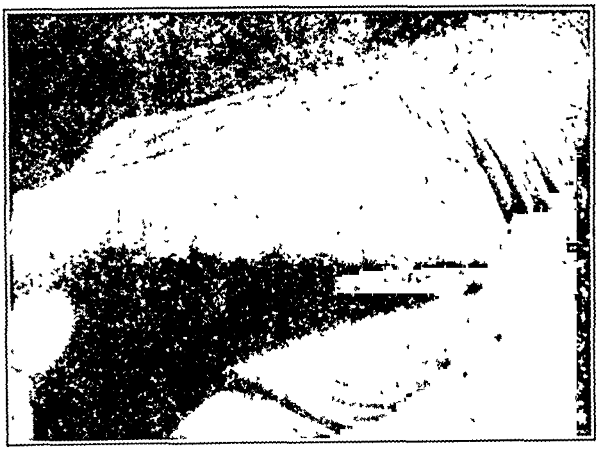
Symptoms.—The onset of illness[5] began Dec. 8, 1936 and was first observed as a small circumscribed vesicle, or papule, appearing on the right thumb, midway between the first and second joints. This lesion became more diffuse and erythematous in character and slowly spread to the fingers, palm and dorsum of the right hand and later to the left hand. Within a few months the infection appeared on both feet, but the lesions did not extend beyond the wrists or ankles at any time.

The skin of the affected areas assumed a darkened, discolored, purplish red color, and sloughing occurred, particularly on the palms of the hands. At least three crops of new skin appeared, each one following the desquamation of the dead tissue. The denuded skin had an offensive odor, and intense itching accompanied the disease process. Suppuration, or the formation of pus, did not occur during the period of illness.

The general systemic symptoms were not pronounced. The highest temperature reported was 101.6 F., but the patient had occasional chills, was mentally depressed, had frequent headaches and experienced arthritic or rheumatic pains, especially in his hips and shoulders.

His appetite was poor; he was debilitated and weak and had a tired feeling. His weight dropped from about 190 pounds (86 Kg.) to 135 pounds (61 Kg.). This state continued for nearly nine months, from Dec. 8, 1936 to Aug 23, 1937. During this period he was unable to work, to dress or to feed himself and was under the constant care of his wife, a trained nurse.



Condition of the hand just prior to treatment.

Finally by the use of roentgen treatments, the application of boric acid ointment and other forms of medication, he improved sufficiently to resume his work on the farm. However, the skin of his feet and hands never became entirely normal, and successive crops of small watery blisters appeared at frequent intervals.

On Oct. 28, 1940, nearly four years after the onset of the first acute attack (Dec. 8, 1936), the patient suffered a relapse, or reinfection, and experienced the same general symptoms as previously described. This period lasted until Jan. 5, 1941—about ten weeks. The initial lesion this time occurred as a watery blister on the second finger of the right hand.

During the second attack he visited a well known clinic and was under observation about two weeks. Cultures from his skin revealed the presence of streptococci, and skin tests for fungous disease proved negative. His case remained undiagnosed and was considered due to possible allergy or exposure to chemical irritants.

A series of treatments prescribed by his physicians, including the use of sulfathiazole ointment, relieved his cutaneous condition somewhat. Some weight was regained and his general health improved, but his hands were never completely free from crops of irritating, itchy, discrete vesicles (see the accompanying illustration). During January 1945 the patient left his Nebraska farm (and the infected swine) and moved to Denver.

By a strange coincidence, through the interest of a mutual friend, a layman who previously had worked in a hog cholera serum plant, this man's plight came to my attention. A specimen of blood from this man was requested, which was secured by his family physician, A. W. Metcalf, M.D., of Denver, and subjected to laboratory testing.

Laboratory Data.—The patient's serum was first tested for brucellosis by both the rapid plate and tube agglutination methods. The results were negative for each in titers of 1:25, 1:50, 1:100, 1:200 and 1:400. A more complete and detailed history was then obtained, which revealed contact with diseased hogs and a chronic urticarial cutaneous involvement. This evidence led to the testing of the serum for possible erysipeloid infection, which testing gave positive reactions in titers of 1:25, 1:50, 1:100, 1:200 and 1:400. In the absence of rapid plate antigen at this time, the tube method was used and the antigen applied was prepared from a proven swine strain of E. rhusiopathiae. Later the serum was checked by the plate method, using the rapid antigen prepared by the Bureau of Animal Industry; the results obtained were comparable with those from the tube method.

After serologic evidence of probable swine erysipelas infection had been obtained, I attempted to recover the organism on culture from small vesicles on the hands. Repeated efforts failed to demonstrate E. rhusiopathiae. The only bacteria recovered were gram-positive cocci commonly found on the skin.

Schoening and Creech[6] have recorded their serologic observations on erysipelas in swine, also in a single acute human case (positive in a dilution of 1:1,000) of erysipeloid. The results on the latter are summarized as follows: "Although no bacteriological confirmation of the diagnosis of infection with Erysipelothrix rhusiopathiae in this case was obtained, the history, clinical symptoms, and results of the serologic tests leave little doubt as to the correctness of the diagnosis. The agglutination reaction parallels rather closely the results obtained in certain types of infection in swine."

Ehrlich[1] reported a case of erysipeloid in a farmer following the slaughter and dressing of a sick hog. The diagnosis of infection due to erysipelothrix was largely established by the rising titer of agglutinins in the patient's serum and by the presence of characteristic bacilli in sections of a cutaneous lesion. The Pathological Division of the Bureau of Animal Industry of the United States Department of Agriculture made the agglutination tests on samples of serum from the patient which proved positive in a titer of 1:1,000. The antigen used was prepared by the Bureau of Animal Industry, and the same type of antigen was used in making the agglutination tests on the case herein reported. On cultures the bureau also recovered E. rhusiopathiae from the skin and joint lesions of the infected hog slaughtered by the farmer, and intensive treatment with penicillin effected a complete recovery of the patient in Ehrlich's case.

Treatment.—After the positive serologic laboratory observations for erysipeloid were made, the probable diagnosis was discussed with the attending physician, who decided to treat the patient with penicillin. Injections of 25,000 units of penicillin were begun March 19, 1945 and made every three hours intramuscularly until 600,000 units had been administered.

Frequent observations on this patient during two years following the penicillin therapy showed that he had completely recovered from the distressing symptoms experienced for nearly nine years prior to treatment.

His mental outlook, facial expression and general appearance had changed decidedly. He has regained his normal weight. The cutaneous lesions and itching have completely disappeared, and the arthritic pains are forgotten. Thus far no recurrence of the troublesome lesions of the skin has appeared, and he has been steadily employed during this period and acts and feels "like a new man."

About one year after treatment with penicillin the blood from the patient, discussed in the present paper, was again tested for E. rhusiopathiae by the rapid plate antigen method, with negative results, in a titer of 1:25 and upward.

---

[5] The information relative to the case history, circumstances and symptoms herein reported was secured from repeated questioning of both the patient and his wife

[6] Schoening, H. W., and Creech, G. T., Serological Studies of Swine Erysipelas with Particular Reference to Agglutination, J. Agric. Research, Jan. 1, 1938, pp. 71-79.

SUMMARY

1. The source of infection in a man with a chronic case of probable erysipeloid of nearly nine years' duration was doubtless on a hog ranch where swine erysipelas was present.

2. Serologic tests with swine erysipelas antigen gave positive results for the organism Erysipelothrix rhusiopathiae in a titer of 1:400.

3. Treatment with 600,000 units of penicillin cleared up the lesions, and there has been no recurrence after two years.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

The Council has authorized publication of the following statement.

AUSTIN SMITH, M.D., *Secretary.*

ALLERGASOL (CHEMTRONIC LABORATORIES):

Racemic Epinephrine, C. O. D.

According to letters and mimeographed advertising circularized through the mails by Chemtronic Laboratories, 194 Malvern Street, Newark 5, N. J., physicians are being offered participation in a promotion scheme to sell a solution of racemic epinephrine under the name Allergasol, to be used with a nebulizer, for inhalation therapy of asthma, and as a spray or eyewash for the eyes in hay fever.

The firm's proposal offers what is termed a streamlined distribution plan, according to which physicians are requested to send in the names and addresses of patients who are to receive Allergasol, and it will then be mailed to them directly C. O. D. The scheme reveals itself in the following statement: "As this is a repeat.item, we will watch the frequency of the first reorders and then arrange to have the solution arrive before they run out." The words "run out" might have special significance for the patients!

The "plan" unfolds as an offer for a 25 per cent physician's discount, on the original and all reorders, that is to be remitted by check every three months, "timed to arrive just before income tax payments are due, and before Christmas" The cooperation of the physician is sought by the following confidences:

"We must work out a cost schedule under this method of operation, so have purposely priced the solution at $3 for the start. The final price will reflect all economies. Your part in this plan can be summed up this way, you recommend and make just one list of your patients, we do everything else, you are not bothered at all on repeat orders."

The final "come on" to the physician appears in the following paragraph:

"You are one of the first of a selected list of physicians to receive this plan. Your suggestions and comments will be invaluable to us. The consensus of opinion as expressed on the question blank, will determine future changes in the plan, the directions, the literature and even the name of the product. Our purpose is to get the best product to the patient at the least cost, we feel sure that this is a mutual aim. Altho the plan is radical, do you consider it unethical? Every phase of our association must meet with your approval, if this plan is to succeed. Please let us have your list of patients as soon as possible."

The "plan" includes a yes-no questionnaire that provides a space for listing allergy patients and the names of individuals merely known to be allergic. The physician is asked if he would suggest that the firm follow the usual methods of distribution, even if it meant a $5 price. The "plan" is thus nothing more than an ill disguised scheme for prescribing by mail in which the physician is enjoined to play the part of accessory.

Allergasol itself is marketed in sealed 1 ounce brown glass bottles labeled "The Scientific Inhalant Relief For Non-Cardiac Asthma Paroxysms, Also Hay-Fever and Similar Allergies, To Be Used Only with Glass Nebulizer." Superimposed on the center panel of the label, in red script, is the statement "With 25 mg. Vitamin C Added." The side panel bears the following statement of composition:

> Each fluid ounce contains .75 g. Epinephrine Hydrochloride crystals. .015 g. Benzoic Acid, .15 g. Cloretone (Chloroform derivative) .0225 g. Sodium Bisulfite as preservatives in Glycerine base solution.

The bottled solution is accompanied by a package circular of instructions for users that is apparently designed to comply with federal drug regulations. Curiously, the package circular is concluded with the designation "1:100 U. S. P.," whereas according to the label the solution represents a 2.5 per cent concentration (1:40) and is elsewhere claimed to contain racemic epinephrine!

The "plan" is circularized with a mimeographed advertising piece that offers a curious hodgepodge of unsupported statements intended to persuade the unwary of the advantages of Allergasol. The premise on which arguments in its behalf are presented are so faulty that only the more credulous will fall prey to such advertising.

The claimed advantages for racemic epinephrine as opposed to levorotatory epinephrine U. S. P. have been previously shown by the Council to be groundless.[1] The claim that the dextrorotatory component of racemic epinephrine is longer acting than the more potent levorotatory epinephrine, and that together these exert a synergistic effect, has not been demonstrated to offer any therapeutic advantage in the use of epinephrine. Indeed, because of the lesser potency of d-epinephrine, racemic or dl-epinephrine can be expected to have only slightly more than half the potency of l-epinephrine (U. S. P.), when solutions of equimolar concentration are compared; a fact admitted by purveyors of racemic solutions by the simple declaration that they contain an amount equivalent to more than twice the concentration of the official solution of epinephrine hydrochloride 1:100 (0.1 per cent)!

The statement that an improvement in the commercial production of the hydrochloride crystals renders Allergasol more stable and less irritating is as meaningless as it is utterly foolish. The claim that Allergasol will not oxidize as readily as other epinephrine solutions is obviously based on the declared presence of two commonly added antioxidants, chlorobutanol (chloretone) and sodium bisulfite, that are supplemented by the addition of ascorbic acid to render the solution further resistant to oxidation. The statement that "the use of this vitamin in such a manner has a healing and non-irritating effect on the lung tissues" is a misrepresentation that cannot be supported by scientific evidence. The point made that, "as epinephrine is quickly decomposed by iron salts and alkalis, an all glass nebulizer has to be used with this solution" represents another attempt to inspire confidence by restatement of a known fact. One may well question the claimed resistance to oxidation of Allergasol that at the same time requires protection from light provided by the brown glass bottle in which it is marketed. All the "hullaballoo" over the ability of Allergasol to withstand deterioration may be appropriately classified as "stable" nonsense!

The crowning insult of the promoter's advertising lies in the statement that:

"The patient can administer treatment himself with safety, as only the actual amount of epinephrine needed to bring relief is taken, and this amount is very small."

The unsupervised use of orally inhaled epinephrine is potentially dangerous from the point of view of overdosage in patients unsuited or unaccustomed to its effects. Epinephrine "fast" asthmatics may not obtain relief even by overdosage with oral inhalations—the real hazard of unsupervised self medication with such a potent drug!

The Council cannot too strongly condemn the vicious character of promoters' schemes that are more interested "by hook or crook" in sales volume than in the welfare of the patient, economic or otherwise. Physicians who have read the other reports of the Council will recognize the familiar patter associated with the promotion of questionable practices. While the names may differ the selling talk is usually the same, regardless of the nature of the scheme immediately concerned.

---

METHIONINE IN HUMAN NUTRITION

Methionine and cystine are the only two sulfur-containing amino acids. Methionine is considered essential for animal growth, as it can substitute completely for cystine, whereas the opposite is not true. Early in the history of research on nutrition it was noted that the addition of small quantities of cystine improved the nutritive value of casein. This fundamental observation was first made in 1915 by Osborne and Mendel.[1] Casein, however, is not the only protein in milk, and lactalbumin was shown not to share this defect. In the nutrition of babies these facts seemed to explain in part the nutritional superiority of mother's over cow's milk, since the protein content of the former contains 60 per cent lactalbumin as compared with about 15 per cent in cow's milk. These considerations presumably did not apply to the adult, because the amino acid requirements for maintenance are less urgent than for growth. Early studies by Madden, Hoehren, Waraich and Whipple[2] indicated that cystine was a key amino acid for the regeneration of serum protein in adult dogs. Kemmerer and Heil[3] obtained the same effect with methionine shortly after. More recently, Croft and Peters[4] found that the addition of a small amount of this amino acid to the diet of adult rats previously burned enabled them to achieve nitrogen balance not possible in the controls. These authors made the suggestion, therefore, that methionine or a protein containing a large percentage of it might be of some therapeutic value in the nutrition of the sick, particularly those subjected to injury. A number of clinical observations during the war were made on patients with hepatitis; the addition of methionine seemed to exert a favorable clinical effect. This therapeutic idea aroused much interest, although the evidence is hard to evaluate. Dissenting data as to the value of methionine supplementation in man were reported by Riegel, Koop and Grigger,[5] who obtained negative results in 14 patients, particularly following operations. Confirmatory negative evidence was reported by Johnson, Deuel, Morehouse and Mehl,[6] employing diets containing a mixture of proteins.

More information was obviously needed, both in animals and in human beings. Such data have recently been reported by a group of investigators, Cox, Mueller, Elman, Albanese, Kemmerer, Barton and Holt,[7] who combined the research facilities of a pharmaceutical house, Mead Johnson and Company of Evansville, Ind., and two universities, Washington University of St. Louis and New York University of New York. These studies show definitely that there is a clear difference between human beings and animals with regard to their respective requirements for methionine, not only for growth, but also for nitrogen balance. Observations were made on rats, on dogs and on human beings. In dogs, the addition of small amounts of methionine was shown to improve the degree of nitrogen retention following the intravenous and subcutaneous injection of a casein hydrolysate. This property was not shared by the addition of any of the other essential amino acids. In rats the same hydrolysate was shown to give a greater average gain in weight with a supplement of methionine. In striking contrast, the observations on human beings were entirely negative. The first group consisted of 3 patients with pyloric obstruction, being prepared for operation, who were fed entirely by vein. The addition of methionine to the casein hydrolysate did not influence the magnitude of nitrogen balance. The second group consisted of 2 normal infants who were given the same casein hydrolysate by mouth. The amount of nitrogen retained and the gain in weight, compared during five day periods before and after the substitution of a small amount of methionine for the same amount of nitrogen in the feeding, did not show a significant difference. The third group consisted of 10 adult volunteers divided into two teams. One received a maintenance level of nitrogen and the other, following a twenty-one day period of protein starvation, received a level of nitrogen approximately equal to the endogenous loss. Differences were not found in the degree of nitrogen retention in either series, whether or not the methionine content of the casein hydrolysate was increased. Since the principal difference between casein and lactalbumin is in their relative content of the sulfur-containing amino acids, it is justifiable to interpret these data by a supplemented casein hydrolysate in terms of the two intact proteins.

These results are so striking and consistent that they indicate a greater need for sulfur-containing amino acids in animals than in human beings, not only for maintenance, but also for growth. The authors suggest that this fundamental difference may be due to the fact that the animals studied were covered with hair. Since hair contains large amounts of cystine, it is reasonable to suppose that the requirement of the rat and the dog for this amino acid or methionine is considerably greater than that of man. Whether or not this explanation is true, the results emphasize again a basic admonition in biologic work: observations made on animals do not necessarily apply to man. The results have a great practical bearing in considering the nutritive value of milk proteins, which are widely used as a source of human food. Casein has long been considered inferior to lactalbumin because of its lower content of the sulfur-containing amino acids. This is apparently true only when it is fed to fur-bearing animals. But man requires less of this essential amino acid, and it is most reassuring that the protein efficiency of the two proteins of milk are therefore of the same order for man. The specific therapeutic virtues that have been attributed to methionine by a number of investigators should be carefully reevaluated. This present study clarifies much of the confusion which now exists as to the nutritional requirements for methionine in man.

SUPERIOR PULMONARY SULCUS PRESSURE SYNDROME

It has been pointed out by Fulton [1] and others [2] that the so-called Pancoast syndrome was first described by Edward Selleck Hare [3] in 1838, at which time Hare was house surgeon at the Stafford County General Infirmary in England. Hare's patient complained of pain, tingling and numbness of the left arm, corresponding to the distribution of the ulnar nerve. There was a small tumor in the "inferior triangular space." Hare attributed the pain to involvement of the brachial plexus and observed that "the pupil of the left eye became contracted and the levator palpebrae ceased to perform its office." Necropsy revealed:

> . . . a tumor process the hardness of scirrhus . . . extending under the sterno-cleido-mastoideus and trapezius . . . and was seen to extend upward as far as the origin of the brachial plexus. The carotid artery, internal jugular vein and pneumogastric nerve passed into its substance, the first remaining pervious, the two last were lost and transformed into the diseased structure, as was also the phrenic nerve and, farther down, the sympathetic, with its lowest cervical ganglion. The tumor lay upon the 3rd and 4th nerves of the plexus, both of which were inseparable from it.

Nearly a century later Pancoast [4] described the same syndrome almost exclusively on the basis of roentgenologic evidence. According to Pancoast it is characterized by constant localization of an epidermoid carcinoma in the superior thoracic inlet adjacent to the pulmonary apex, the site of origin being independent of the neighboring lung, pleura, ribs, vertebrae and mediastinum or of metastatic foci. Clinically, the components are Horner's syndrome, indicating involvement of the cervical sympathetic nerve; pain referred to the shoulder, arm and hand associated with muscular atrophy, indicative of invasion of the brachial plexus; the presence in the roentgenogram of a small homogeneous apical shadow together with signs of destructive infiltration of contiguous ribs and vertebrae. Pancoast believed that the tumor was of branchial origin because of its constant localization in the region where branchial clefts are apt to persist, because of the absence of any other demonstrable focus and, finally, because in one case where tissue was removed for biopsy microscopic examination showed a squamous carcinoma in which the changes were compatible with those of an epithelial new growth of branchiogenic origin. However, it has since been shown that practically any form of pressure, if properly applied, may cause the syndrome in question. In the cases reviewed by Morris and Harken [2] the tumor which produced the symptoms by pressure was probably of branchiogenic origin in 20, osteogenic sarcoma in 2, sympathicoblastoma in 1, metastatic gastric carcinoma in 1, metastatic mammary carcinoma in 1, metastatic hypernephroma in 1 and cancer of the thymus in 1. Morris and Harken pointed out that there are several instances in which the syndrome was caused by the pressure of an aneurysm, apparently the first description of this sort having been found in the Bellevue Hospital necropsy records for the year 1868, or one year before Horner described the syndrome which bears his name.

Thus it appears that Hare described what is now called Horner's syndrome thirty-one years before the ophthalmologist Horner described it and what is now called Pancoast's syndrome ninety-six years before Pancoast described it. From all that is known of the remarkable syndrome due to pressure at the superior pulmonary sulcus it seems that the condition was first described by Hare and that the eponymic distinction belongs to him.

Current Comment

THE DOCTOR AND VOCATIONAL REHABILITATION

Physicians will shortly receive through the mail a booklet entitled "The Doctor and Vocational Rehabilitation for Civilians" prepared for their special information by the Office of Vocational Rehabilitation of the Federal Security Agency. This describes an exceedingly important medicosocial activity in which every practicing physician has a considerable stake. Successful rehabilitation for civilians under the present statutes cannot operate successfully without the honest and wholehearted cooperation of medical practitioners. This state-federal vocational program has provided itself with excellent medical and technical advice respecting general policy and administration. But the individual physician must discover eligible candidates, conduct the preliminary physical examinations and in most cases manage the physical restoration phases of the rehabilitation process. There are thousands of eligible candidates for rehabilitation. Each year the number of new cases constitutes in itself an enormous clinical and training problem. At present every state and territory is actively engaged in this work. The booklet has been prepared by the medical staff of the Office of Vocational Rehabilitation. Apparently this federal agency in company with appropriate state agencies is striving to administer a public program in a manner acceptable to physicians.

ANTHRAX

Heretofore human anthrax has been considered a rare disease limited almost entirely to persons engaged in the leather and hide industries or living in agricultural regions. A recent survey by the U. S. Public Health Service of the period from 1939 to 1943 showed not only a 16 per cent increase of cases of anthrax for that period, but that the infection occurred in people who did not have occupational contact with infected material. One patient was a child living in a mining location in a state where animal anthrax had been unknown for ten years. Other patients were housewives, some of whom had been gardening; other persons contracted the disease from tooth brushes, shaving brushes and a fur coat. Cowdery[1] reports the unusual occurrence of pulmonary anthrax with septicemia in a man aged 46 who apparently had none of the usual means of acquiring the infection. He points out that human anthrax is not rare in the United States. A review of the literature, however, indicated that pulmonary anthrax was extremely rare until recently. In the last ten years he said only one detailed report of a case of primary internal anthrax had appeared. Cowdery believes that physicians can no longer consider anthrax as being limited to industrial and agricultural areas but that the disease may occur almost anywhere.

METHYLATED XANTHINES AND BLOOD CLOTTING

Methylated xanthines have been widely used for years in the treatment of certain conditions involving the clotting activity of the blood, such as coronary thrombosis. Since it has been reported that methylated xanthines in experimental animals increase the prothrombin level of the blood and increase its coagulability, it is important to know whether any adverse effect might follow such administration. Gilbert and his colleagues[1] carried out studies on human beings and dogs to determine whether or not the prolonged administration of methylated xanthines has any effect on clotting activity. Neither the animal experiments nor the clinical observations, which were based on 25 patients chosen at random, revealed any changes in prothrombin time, clotting time of the blood or heparin curve as the result of the administration of these drugs. The obvious deduction is that the administration of methylated xanthines will not be harmful as far as the clotting mechanism of the blood is concerned.

CANCER CELLS IN PROSTATIC SECRETIONS

Herbut and Lubin[1] note that not more than 20 per cent of all cancers of the prostate are amenable to radical intervention when first seen. The improvement in the diagnosis of pulmonary carcinoma through examination of bronchial secretions suggested that the cytologic method may be useful in the diagnosis of cancer of the prostate. Mulholland[2] of the Mayo Clinic reported on this method fifteen years ago but did not follow up his original report. In the procedure advocated by Herbut and Lubin prostatic secretions are obtained by massage and stained by the Papanicolaou technic. The criteria for the diagnosis of carcinoma from prostatic secretions are (1) the presence of an unusual number of multicolored pavement cells and (2) the presence of cancer cells. Although the significance of the pavement cells is not clear, these authors believe that they are derived from the urethra and that they are specific for carcinoma because they have not been encountered in any of the smears from noncancerous patients. However, the more important criterion is the identification of cancer cells. Their neoplastic character is proved by the fact that they are found only in cases of carcinoma and that they are identical with cells encountered in smears of the tumor tissue itself. The problem of identifying cancer cells in prostatic secretions is much easier than it is in vaginal or bronchial secretions because the prostatic secretions from noncancerous patients contain only a few epithelial cells. The authors have examined prostatic secretions from 100 patients and made a cytologic diagnosis of carcinoma in 17 of these. This diagnosis was confirmed histologically in 10 of these cases and was reasonably certain clinically in an additional 6.

ORGANIZATION SECTION

Official Notes

THE 1948 ANNUAL SESSION

The Ninety-Seventh Annual Session of the American Medical Association will be held in Chicago June 21 to 25, 1948. It is probable that on Sunday, June 20, preceding the first day of the session there will be various meetings and conferences for which arrangements will be made by the Association.

Council on Medical Service

MIDDLE ATLANTIC STATES REGIONAL CONFERENCE ON MEDICAL SERVICE

May 22, 1947

The midyear meeting of the Middle Atlantic States Regional Conference on Medical Service was held in Philadelphia, May 22. This conference is a permanent organization composed of six state medical societies: New York, Pennsylvania, Virginia, New Jersey, Delaware and Maryland. Organized in 1945, the conference has held meetings semiannually. The present officers are Dr. F. F. Borzell, Philadelphia, chairman; Dr. T. A. McGoldrick, Brooklyn, vice chairman, and Dr. W. M. Bates, Philadelphia, secretary-treasurer.

The program for the May 22 meeting was in the form of round table discussions on:

1. Present Status of United Mine Workers Health Program.
2. Organized Medicine's Relationship to the Various Cancer Drives.
3. The Present Taft-Smith-Ball-Donnell bill.
4. The Hill-Burton Hospital Construction Act.
5. Changes in the medical policy of the Veterans Administration.

Status of U. M. W. Health Program.—Dr. Walter B. Martin, Norfolk, Va., a member of the Council on Medical Service of the American Medical Association, acted as moderator. Dr. Louis W. Jones, Wilkes-Barre, Pa., chairman of the Medical Economics Committee of the Medical Society of the State of Pennsylvania, presented a summary of the U. M. W. program, which was followed by a discussion participated in by representatives of the various states present. The general conclusions were "that the profession has a definite obligation and opportunity to serve the mining communities; that this principle is extendable to all industry; that, wherever it is evolved, it must be applicable as a community service and not be limited to relatively minor groups."

Organized Medicine's Relationship to the Various Cancer Drives.—Dr. E. J. McCormick, Toledo, Ohio, chairman of the Council on Medical Service of the A. M. A., acted as moderator. Dr. James R. Miller, Hartford, Conn., a member of the A. M. A. Board of Trustees and Chairman of the Service Division of the American Cancer Society, spoke briefly on the program of the American Cancer Society. Dr. Miller brought out the following fundamental principles:

1. Cancer is only one of the diseases which need a program.
2. The service program must be experimental.
3. The program must be on a professional level.
4. It must encourage the widest possible use of the regular physical examination.
5. It must assist and not compete with practitioners of medicine.
6. It must have the approval of the county medical societies.

Dr. James Crabtree, Washington, D. C., Deputy Surgeon General, U. S. P. H. S., outlined the work of the Public Health Service in the field of cancer control. Dr. Crabtree gave the main problems as:

1. Shortage of trained personnel.
2. Lack of physical facilities for research.
3. Lack of a long term policy by both governmental and private agencies.

State reports and points of view were given by Drs. Aranow, Bauckus, Borzell, Clair, Hines and Pendergrass. Summarizing this round table, the conference seemed fairly much in agreement on the following points of view:

1. Screening examinations have no place in a state program. It is a job for the general practitioner.
2. Screening examinations in detection clinics should be supported as an experimental approach.
3. There is need for editing the publicity used in fund raising drives to make it acceptable and accurate.
4. The profession and the public need educating.
5. More facilities for the care of incurable cases are needed.

Hill-Burton Hospital Construction Act.—The present status of the Hospital Construction Act was discussed by Dr. James Crabtree and Dr. Frederic J. Quigley. It was brought out that all but one of the fifty-two states and territories have designated an agency to carry out the required survey. One of the serious problems which seems to be facing state agencies is the determining of priorities, and from the discussion it seemed evident that it will be difficult to get facilities into those areas which need them most. The act was criticized in that it imposed a five year limit and in that it requires reasonable assurance for maintenance of facilities without also providing a continuing aid through the states where the need was demonstrated. These deficiencies are not correctable at the administrative level and can be altered only by amendments to the act itself.

Taft-Smith-Ball-Donnell Bill.—Mr. J. W. Holloway Jr., Director of the A. M. A. Bureau of Legal Medicine and Legislation, reported on the Taft bill S. 545. Several deficiencies in the bill were pointed out during the discussion. Among these are that:

1. The several states should each be allowed to designate the administrative agency preferred and not be limited to "providing that on or before 1949 such agency shall be the State health agency" (sec 712 [a] [1]).
2. It is inconsistent with parts 2, 3 and 4 of the American Medical Association's Ten Point Program, which provides for the use of tax funds only when need can be shown.
3. There is no guaranty of freedom of choice of physician in the bill.

Veterans Administration Medical Policy.—Dr. James C. Harding, assistant medical director for auxiliary services of the Veterans Administration, spoke on the Home Town Medical Care Program, stating that, while there is no change in the overall policy of the Veterans Administration, certain conditions have required administrative changes. Among such changes are:

1. Uniform fee schedule format, which, while actually a maximum set of fees, may be deviated from if "cause" is shown.
2. Certification by physicians in some states to the effect that the fees charged are not higher than those charged nonveteran patients.
3. A limitation of $6,000 annually wherever doctors are paid on a fee basis. A limitation on free choice of physician and examination to determine service connected pension rating.

Much discussion followed Dr. Harding's presentation and was participated in by all representatives present. The discussion brought out differences of opinion concerning Dr. Harding's statements, particularly with reference to the fact that the philosophy of the Washington office of the Veterans Administration has not permeated the regional offices. The representatives of the states all seemed to be of the opinion that there has been a gradual withdrawal of free choice of physician under the Home

Town Medical Care Program and that the Veterans Administration is attempting to change the original agreements

The conference voted unanimously to bring its deliberations to the attention of the House of Delegates of the American Medical Association through a report to the Council on Medical Service prepared by Dr George S Klump, representative of the Board of Trustees of the Medical Society of the State of Pennsylvania

Washington Letter

(From a Special Correspondent)

July 9, 1947

Six Agencies Accused of Using Health Workshops as Propaganda

The Subcommittee on Publicity and Propaganda, in an interim report approved by its parent group, the House Committee on Expenditures in Executive Departments, has accused six federal agencies of using government funds improperly for propaganda activities in planning and conducting "health workshops" to support pending legislation Chairman Forest A Harness Republican of Indiana requested the attorney general to initiate proceedings to halt the use of public funds in this manner Named in the report as having been 'known to have participated in this campaign" are the U S Public Health Service, Children's Bureau, Office of Education, U S Employment Service, Department of Agriculture and Bureau of Research and Statistics of the Social Security Board The committee charged that key personnel in these agencies planned to set up the workshops in strategic areas to influence farm and labor leaders to "build up an artificial, federally stimulated public demand on Congress for enactment of the Wagner-Murray-Dingell bill *providing compulsory health insurance* ' Workshops were reported to have been held in St Paul and at Jameston, N D

Survey Reports on Causes of Nurse Shortage

The Bureau of Labor Statistics of the Department of Labor reports that most nurses who leave the profession do so to marry rather than to take other jobs This was based on a study made by the agency with the National Nursing Council and the Women's Bureau of the Department Ewan Clague, commissioner of labor statistics, says "The present nursing shortage is apparently primarily due to increased demands for nursing service at a time when many married nurses are leaving their profession, and many potential nursing students find other fields of employment more attractive"

Officers Named to Silver Spring Laboratory

Dr L R Hafstad, director of Research of Johns Hopkins University's Applied Physics Laboratory at Silver Spring, Md, has been appointed secretary of the Joint Research and Development Board, succeeding Lloyd V Berkner, who resigned to devote full time to research Dr Isaiah Bowman, president of Johns Hopkins, also announced the appointment of Dr Ralph E Gibson as acting director Dr Hafstad won the 1946 President's Medal for Merit, awarded for wartime service in development of ordnance devices for the Army and Navy

Senate Group Approves Joining World Health Organization

The Senate Foreign Relations Committee has approved legislation providing for American participation in the World Health Organization which would establish world health and drug standards, set up sanitary requirements and create uniform drug advertising and labeling The committee reserved the right for the United States to withdraw on ninety days' notice American financial support would be about 2 million dollars a year

Government Discontinues Giving Amputees Free Automobiles

The government has discontinued its program of giving free automobiles to amputee war veterans The Veterans Administration's last accounting revealed that 13,000 veterans have received automobiles, and applications of several thousand others had been approved

Medical Legislation

MEDICAL BILLS IN CONGRESS

Department of Health, Education and Security

The Senate Committee on Expenditures in the Executive Departments has favorably reported S 140 with an amendment, proposing to establish a federal Department of Health, Education and Security The reported bill proposes to create in the department three bureaus, a Bureau of Health, a Bureau of Education and a Bureau of Public Welfare, each to be headed by an undersecretary The qualifications to be possessed by these undersecretaries are not specified in the bill as reported To the Bureau of Health will be transferred the United States Public Health Service the Food and Drug Administration, Freedman's Hospital and St Elizabeths Hospital To the Bureau of Education will be transferred the United States Office of Education, Howard University, the American Printing House for the Blind and the Columbia Institution for the Deaf To the Bureau of Public Welfare will be transferred the functions of the Social Security Administration including the Children's Bureau The Secretary of the Department and the undersecretaries are to be appointed by the President, subject to the approval of the Senate

Postgraduate Schools of Public Health

A bill introduced by Senator Taft, Ohio as S 1455 proposes to amend the Public Health Service Act to provide grants to postgraduate schools of public health For each fiscal year there will be authorized to be appropriated a sum sufficient to enable the Surgeon General of the United States Public Health Service, through grants to postgraduate schools of public health to assist in improving the training available in the field of public health and in increasing the number of individuals adequately trained in such field There will also be authorized to be appropriated from time to time such sums as may be necessary to enable the Surgeon General to make grants for the construction of buildings and other facilities necessary to carry out the purposes of the legislation

National Heart Disease Act

A bill introduced by Representative Javits New York, as H R 3762, provides for the establishing in the Public Health Service a division of the National Institute of Health to be known as the National Heart Disease Institute in which researches, investigations, experiments and demonstrations relating to the cause, prevention and methods of diagnosis and treatment of the diseases of the heart and circulation will be conducted Provision is contained in the bill, too, for grants in aid to the states, counties health districts and other political subdivisions of the states for the establishment and maintenance of programs for prevention, treatment and control of heart diseases including the provision of appropriate facilities for care and treatment and including the training of personnel for state and local health work There will be a National Heart Disease Council to consist of the Surgeon General of the Public Health Service or his representative the chief medical officer of the Veterans Administration or his representative, the Surgeon General of the Army or his representative, the Surgeon General of the Navy or his representative, and twelve members appointed by the Surgeon General with the approval of the Federal Security Administrator

Cancer Research

A bill making appropriations for the Executive Office and sundry independent executive bureaus boards commissions and offices for the fiscal year ending June 30 1948 H R 3839, in making an appropriation for the Atomic Energy Commission earmarks a sum not to exceed $25,000 000 to be available for research work in connection with the control of cancer

Admission to Public Health Service Hospitals

H R 3784 introduced by Representative Chapman Kentucky proposes to authorize the United States Public Health Service to admit to its hospitals persons committed by state courts who are beneficiaries of the service or who are narcotic addicts

Miscellaneous

A bill introduced by Representative Blackney, Michigan as H R 3831 has been favorably reported to the House of Representatives proposing additional inducements to physicians, surgeons and dentists to make a career of the United States military, naval and Public Health services A similar bill has been introduced in the Senate by Senator Pepper, Florida, as S 1511

Senator Langer, North Dakota has introduced S 1428, proposing to amend the United States Employees Compensation Act so as to permit chiropractors to treat the beneficiaries of that act

A bill introduced by Representative Howell, Illinois, as H R 3150 has been reported to the House of Representatives without amendment, proposing to amend the Railroad Unemployment Insurance Act by eliminating the provisions in it relating to cash sickness and maternity benefits which were added by the so called Crosser Act enacted by the Seventy-Ninth Congress

Coming Medical Meetings

Alaska Territorial Medical Association, Fairbanks, July 28 30 Dr William J Blanton, Juneau, Secretary

Bureau of Information

LOCATION OF PHYSICIANS

Virginia Shuler
Chicago

This is the fourth of a series of charts showing the trend in locations of physicians from April 1946 to January 1947, the first series appeared May 17, the second May 31 and the third June 14.

The Commonwealth Fund through its Division of Rural Hospitals has been developing a plan in the Rochester, N. Y., region to bring together in close affiliation the hospitals located in the area and in Rochester.

The essence of the plan is to determine whether "concerted voluntary action by the hospitals through representative organization on a regional scale" will help significantly in bringing about further progress in rural medicine. The premises for such a plan are twofold: that isolated hospitals in small towns need long-continued aid and counsel from outside sources if they are to rise to the full measure of their opportunities, and, second, that the natural sources from which such aid and counsel should come are the urban hospitals. The proposed region is designed to link a geographically coherent group of small hospitals with the large hospitals in an accessible center.

The experience gained in this regional health experiment is intended to serve as a pattern for other areas in the country. It is entirely a voluntary effort of the regional hospitals to build a more coherent medical and nursing program dependent on the individual participation of the physicians in the area.

"Today Michigan practitioners total approximately 5,150 but on the basis of one doctor of medicine per 850 people, Michigan needs 1,200 more practitioners. During the past twelve to eighteen months Michigan physicians returned from military service and relieved the critical situation to some extent; also some new physicians have located in various spots in Michigan through the aid of the Placement Bureau of the Michigan State Medical Society. However, it would appear that the shortage of doctors of medicine will continue until those young physicians who are still in military service are released for civilian practice."

Mr. William J. Burns, Executive Secretary,
Michigan State Medical Society,
?020 Olds Tower, Lansing.

"There has undoubtedly been some tendency in Wisconsin for the concentration of physicians to shift from the rural to urban areas. The study conducted for the last eight months of 1946 shows fifteen rural counties with fewer physicians than at the start of the period studied.

"But it is important to appreciate that the postwar shifting and relocation of physicians in Wisconsin is not as yet completed. Many are in temporary locations while their plans are 'jelled.' Others are doing refresher work. Some are delaying permanent plans until the housing situation is eased. The State Board of Health has conducted a preliminary study of rural health conditions in the state as a whole which indicates no significant shortcoming in the health of rural people as compared with urban. Further studies will be made of specific areas, and legislation is being considered which will permit the appointment of special medical officers in the more difficult areas, it being hoped that physicians holding these appointments will retain their locations as their practice develops. The State Medical Society and county societies are making available complete information to physicians interested in Wisconsin locations. The State Board of Medical Examiners is meeting more frequently than required by law to assure prompt action on applications for Wisconsin licensure."

Mr. C. H. Crownhart, Secretary,
The State Medical Society of Wisconsin,
917 Tenney Building, Madison 3.

"The medical situation throughout Illinois has shown a marked improvement during the past year, and this situation is especially conspicuous in the larger cities. As a matter of fact, there are very few cities of more than 5,000 population that do not have more physicians at the present time than before the outbreak of World War II. Although quite a large number of veteran-physicians have located in the small towns that can support only one or two physicians, there are still several very desirable locations available, and the office of the secretary of this society endeavors to retain accurate information to be submitted to physicians who write for these data. Some of these towns are not conveniently located to hospitals and we are experiencing some difficulty in finding physicians willing to locate in them. Quite a large number of Illinois physicians are taking residencies following their release from military service and intend to specialize rather than returning to general practice. The secretary's office has noted an urgent need for eye, ear, nose and throat specialists throughout the downstate area."

HAROLD M. CAMP, M.D., Secretary,
The Illinois State Medical Society,
Monmouth, Ill.

GOVERNMENT SERVICES

ARMY

THE 110TH STATION HOSPITAL IN VIENNA

This U. S. Army hospital, now located in the former "Kaufmaennische Spital" in Vienna, is providing medical care for about 4,200 military personnel, 1,200 dependents and 800 War Department civilians, patients flown in from American delegations in eastern European countries and authorized members of Allied nations. In addition, during the last year there were 26,000 outpatient treatments, 53 deliveries and 15,000 sittings in the dental clinic.

Owing to its proximity to a famous medical school, this hospital has served as host to medical officers attending graduate courses at Vienna University through arrangements made by the chief surgeon of the European command (The Journal, June 21, p. 719). While the hospital buildings were badly damaged during the war, practically every section has been reconstructed to meet the required high standards of medical care.

The 110th Station Hospital was activated at Camp Pickett, Virginia, in 1942, served in England and Scotland, landed in France in 1945, and later was assigned to occupation duty with the U. S. Forces in Austria. While it operated with the capacity of up to 800 beds during the war, the number of beds now has been reduced to 150. The present commanding officer is Lieut. Col. C. W. Sargent, M. C.

HEALTH IN JAPAN

During March in Japan the incidence of typhus, bacillary dysentery and relapsing fever all decreased. However, typhoid increased from 659 cases in February to 1,409 in March, the highest incidence, 580, having been in the province of Kyongsang-Pukto.

A conference was held March 20-21 in Seoul in which provincial veterinary officers discussed the sanitation of fish markets, slaughterhouses and dairy plants, also the prevention and treatment of animal diseases.

A central committee of fifteen members was chosen at a meeting in Seoul, March 15-16, to work on reviving the Korean Red Cross.

ARMY AWARDS AND COMMENDATIONS

Major General M. C. Stayer

The Legion of Merit has been awarded to Major Gen. M. C. Stayer, M. C., U. S. Army (retired), now of Harrisburg, Pa., for performing exceptionally meritorious service from July 1945 to April 1946 as director of the public health and welfare division, United States Group Control Council (Germany) and chief of the Public Health and Welfare Branch, Internal Affairs and Communications Division, Office of Military Government for Germany (U. S.). General Stayer, states the citation, was responsible for planning, directing and supervising the reorganization of the German medical system, public welfare program, education and religious affairs for the American Zone of Occupation and for negotiating on a quadripartite basis necessary matters pertaining to the whole of Germany. Through his untiring efforts, perseverance and energy General Stayer so successfully accomplished his mission that typhus was practically wiped out of the American Zone, typhoid and other epidemics were averted and his prompt and effective program was of inestimable value in averting situations which might have jeopardized the entire occupation plans. Dr. Stayer graduated from Jefferson Medical College in 1906 and entered the military service in 1909.

Brigadier General Robert C. McDonald

The Legion of Merit has been awarded to Brig. Gen. Robert C. McDonald, M. C., U. S. Army (retired), of Washington, D. C., who displayed exceptionally meritorious conduct in the performance of outstanding services as surgeon, Fourth Service Command, from July 1944 to October 1945. With unusual judgment, foresight and careful planning he accomplished a program of expansion which provided the best of medical attention for many sick and wounded. He effected a reorganization to achieve better supervision of the extensive facilities of the command and guided an efficient program which made the Welch Convalescent Hospital at Daytona Beach, Fla., a model institution. Through his high professional attainments and inspiring devotion to his important tasks General McDonald contributed substantially to the success of American military medicine. Dr. McDonald graduated from Tulane University of Louisiana School of Medicine, New Orleans, in 1909 and entered the military service in February 1911.

Colonel Gustave E. Ledfors

The Legion of Merit has been awarded to Col. Gustave E. Ledfors, M. C., U. S. Army, who as chief of the supply division, Office of Air Surgeon, from October 1942 to January 1945 solved the vital problem of determining the medical supply requirements of the Air Forces, working untiringly to develop and standardize medical equipment peculiar to the Army Air Forces. He made striking reductions in cubage and weight of medical items to save air transport space and effected important economies in materials and parts. Through constant liaison with military, governmental, technical and professional organizations he was able to obtain release on surpluses which were needed by his command and to make short cuts, improvisations and substitutions which insured adequate amounts of the scarcest supplies. He presented requirements for medical field items on a new basis of aircraft production and aircrew members instead of the old troop strength basis and saw his estimates substantiated by later developments. He was largely responsible for the exceptionally fine record of medical supply throughout the far flung installations of the Army Air Forces. He also has been awarded the Bronze Star. Dr. Ledfors graduated from the University of Minnesota Medical School in 1930 and entered the military service in July 1929.

Lieutenant Colonel Clarence S. Livingood

The Legion of Merit has been awarded to Lieut. Col. Clarence H. Livingood, M. C., A. U. S., of Philadelphia, whose contribution to military medicine was made while he was consultant in dermatology, Office of the Surgeon General, during the period March to December 1945. As the citation accompanying the award explains, he was responsible for the practical application of methods of diagnosis and treatment of skin diseases in the Zone of the Interior, thereby insuring that the large number of soldiers with these serious and often intractable diseases received the best possible care their country could offer. Dr. Livingood graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1936 and entered military service Feb. 15, 1941.

Major John H. Dingle

The Legion of Merit has been awarded to Major John H. Dingle, M. C., A. U. S., of Cleveland. The citation read in part as follows: As director of the Commission on Acute Respiratory Diseases, Army Epidemiological Board, and its laboratory from May 1944 to October 1945 he rendered exceptionally meritorious service. Profiting by training and experience as a consultant to the Secretary of War and member of the Commission on Influenza, he contributed the results of his investigations to the Commission on Acute Respiratory Diseases, which under his leadership established the causative agent of atypical pneumonia as being a filtrable virus and added greatly to the current store of knowledge of the common cold, influenza, hemolytic streptococcic infections and other respiratory diseases of importance to the Army. Throughout the entire period of his service Major Dingle was repeatedly called on by the Surgeon General for assistance in the investigation of unusual outbreaks of respiratory disease in the United States and in overseas theaters. Dr. Dingle graduated from Harvard Medical School in 1939 and entered military service in May 1944

Captain Henry M. Lemon

The United States of America Typhus Commission Medal has been awarded to Capt. Henry M. Lemon, M. C., A. U. S., of Quincy, Mass. The citation read as follows: "He rendered meritorious service in connection with the work of the United States of America Typhus Commission in the control and prevention of epidemic typhus fever in the American-occupied areas of Germany and Austria during the period Nov. 4, 1945 to April 9, 1946. He participated in formulation of the program and in carrying out control measures, contributing directly to the safeguarding of American troops as well as civilian populations from outbreaks of typhus fever." Captain Lemon, who was also awarded the Army Commendation Ribbon, graduated from Harvard Medical School in 1940 and entered the military service in 1943.

Captain Glen V. Ryan

The United States of America Typhus Commission Medal has been awarded to Capt. Glen V. Ryan, M. C., A. U. S., of Indianapolis. The citation read in part as follows: While attached to headquarters seventh Army from April to June 1945 he performed exceptionally meritorious service in connection with the work of the United States of America Typhus Commission. As head of a provisional typhus case finding team Captain Ryan, through his enthusiasm and outstanding initiative, carried out an effective typhus control program in the seventh army area. Working long hours and covering great distances, he uncovered, diagnosed, hospitalized and treated hundreds of typhus cases, performing necessary control measures. At the Dachau concentration camp it was necessary to dust the entire 36,000 inmates as well as the living quarters, and this was accomplished in less than six days by his able and skilled direction. The effectiveness with which he carried out typhus control work is attested by the dramatic cessation of new cases at the end of the incubation period following the initial dusting. Dr. Ryan graduated from the University of Arkansas School of Medicine in 1933 and entered the military service in August 1942.

Captain Hyman B. Copleman

The Legion of Merit has been awarded to Capt. Hyman B. Copleman, M. C., A. U. S., of New Brunswick, N. J. The citation read as follows: "Captain Copleman performed outstanding services from July 28 to Aug. 28, 1944, while chief surgeon of the prisoner of war hospital for Allied personnel at Chalons sur Marne, France. He devoted every effort to providing an adequate surgical service for his fellow prisoners, and, while still a prisoner himself, made contact with advancing American troops to arrange the transfer of wounded personnel to their care." Dr. Copleman graduated from Rush Medical School, University of Chicago, in 1933 and entered the military service June 19, 1942. He has also been awarded the Silver Star with Oak Leaf Cluster, the Bronze Star and the Purple Heart with Oak Leaf Cluster.

VETERANS ADMINISTRATION

REHABILITATION OF SEVERELY INJURED VETERANS

In most of the 126 veterans' hospitals a program is under way to speed the rehabilitation of the severely injured by teaching them a variety of trades and arts. The program also embraces patients whose health requires repeated or continuous hospitalization for chronic conditions. In many cases the instruction will provide the veterans with an opportunity to contribute to their own livelihood after recovery. A group of 30 veterans completely paralyzed from the waist down have progressed so well in the watch making courses that they will continue training at a private school of watch making on Long Island. A group of 75 patients at another veterans' hospital is studying radio and broadcasting technics as a part of their rehabilitation. Several of them have already received amateur radio operating licenses. Among other courses that disabled veterans are taking are photography, automotive repair, engraving, electrical work, metal work, jewelry and agriculture. This type of rehabilitation is available to all patients with the approval of their physicians.

HOSPITAL NEWS

The 89 bed neuropsychiatric building for female veterans at the Bedford, Mass., Veterans Administration hospital has been opened.

Two minor changes in plans for certain veterans' hospitals in the South are (1) the substitution of a 100 bed general hospital in addition to the present hospital at Tuskegee, Ala., in place of a proposed 164 bed neuropsychiatric addition; the present hospital at Tuskegee has a standard capacity of 2,052 neuropsychiatric beds; (2) conversion of the 317 bed hospital for chronic diseases, Atlanta, Ga., to a 225 bed tuberculosis hospital pending completion of a proposed tuberculosis hospital at Americus, Ga. This conversion will be temporary, and on completion of the hospital in Americus the Atlanta hospital will revert to its former type of facility.

NEW SITE FOR BOSTON HOSPITAL

President Truman and the Federal Board of Hospitalization have approved the acquisition of a 9 acre site for a veterans' hospital in Boston, 3 miles from the city's business district, where a 1,000 bed general hospital will be constructed. This site, which is sufficiently close to Boston's three medical schools to assure the cooperation of local personnel as consultants, is being substituted for a previously approved site on Willow Pond Road in Boston.

VETERANS ADMINISTRATION EMPLOYEES

About 87 per cent, or 121,528 of its employees, are veterans, the Veterans Administration announced May 2; this compares with 61.5 per cent in December 1941. In the central office in Washington, 98 per cent of the male employees are veterans. Of the female employees of the Veterans Administration 14,414, or 17.2 per cent, are veterans, widows of deceased veterans or wives of disabled veterans. While in December 1941 only 11.8 per cent of the women employed were in this category, as of March 31 the Veterans Administration had a total of 223,174 employees and about 76,000 of them, or almost 35 per cent, were engaged in medical services to veterans.

CONTRACT AWARDED FOR ST. LOUIS HOSPITAL

The War Department announces that the architect-engineer contract for the 1,000 bed general medical and surgical veterans' hospital at St. Louis has been awarded to firms in that city and Chicago, and construction is expected to start within a year.

CRUTCHES

The Medical and Surgical Relief Committee donated in June, for the use of veterans, $175 worth of crutches and canes, which will be distributed by the orthopedic unit of the Veterans Administration, 252 Seventh Avenue, New York.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CALIFORNIA

Pediatric Unit Opened.—White Memorial Hospital, Los Angeles, opened its $150,000 pediatric unit May 12. At the ceremony a check for $2,000 from the Los Angeles Elks Foundation, to furnish one of the wards in the unit in the main hospital building was accepted.

Scholarships in Chest Diseases.—The Alameda County Tuberculosis and Health Association has reestablished the scholarships for study of diseases of the chest. They are open to young physicians beginning private practice in Alameda County and the work is done in the chest clinics of the county under teaching supervision

Society News.—At a meeting of the Academy of Medicine, Hollywood, May 8, Dr. Herbert Acuff, Knoxville, Tenn., discussed "The Underlying Principles of the Management of Peptic Ulcer."——At a meeting of the Los Angeles Society of Internal Medicine June 4 Dr. Paul E. Steiner, associate professor of pathology, University of Chicago, spoke on "Human Carcinogens."

The Janeway Lecture.—Dr. Robert S. Stone, professor of radiology at the University of California Medical School, San Francisco, who was closely associated with atomic research during World War II, was selected to deliver the Janeway lecture at the meeting of the American Radium Society at Atlantic City. His lecture was entitled "Neutron Therapy and Specific Ionization." The lecture was established in 1933 in memory of Dr. Henry H. Janeway, attending surgeon to the Memorial Hospital, New York, where he established a physical laboratory and did pioneer work in the field of radium therapy. Dr. Janeway died Feb. 1, 1921.

CONNECTICUT

Distribute Cancer Bulletin.—The state medical society and the Connecticut Cancer Society are cooperating in the distribution of a bulletin concerning the medical aspects of cancer. The data included were prepared and published in recent months by the Committee on Cancer of the Illinois State Medical Society. Bound in a loose-leaf handbook, the bulletin is currently being distributed in limited numbers to members of the Connecticut society, for whom it may have the most immediate interest.

State Extends Public Health Program.—Connecticut has only thirteen full time local departments of health, serving about half of the population. They are mainly in large cities. It remains now for local boards of selectmen to vote affirmatively for such a department in rural areas. A new state law appropriating $25,000 for financing district health departments during 1947 to 1949 permits two or more towns, cities or boroughs to unite into a locally self-governing district department of health. The state may provide funds up to half the cost of operating such a department, but the total amount available annually to any one town, city or borough may not exceed $4,000, nor the total state aid to any district $20,000.

Commission to Improve Mental Hospitals.—Drs. Joseph H. Howard, Bridgeport, and Joseph I. Linde, New Haven, have been appointed by Governor James L. McConaughy to a commission to inaugurate a $7,000,000 improvement program for the state's mental institutions. Past president of the Connecticut State Medical Society, Dr. Howard is a member of the state commission on the care and treatment of the chronically ill, aged and infirm. He was recently named president-elect of the conference of presidents and other officers of state medical societies at the annual meeting of the organization in Atlantic City. Dr. Linde, president of the State Medical Society in 1940, is health officer for the city of New Haven and is a member of the State Tuberculosis Commission.

The Winslow Seminar Fund.—Professor Charles-Edward A. Winslow was honored at a recent dinner in New Haven by 150 faculty associates and graduates of the Yale department of public health, which he organized and served as its chairman for thirty years until 1945. He was presented with the first copy of the March 1947 *Yale Journal of Biology and Medicine*, which is devoted entirely to papers by his former students and colleagues as well as a bibliography of 574 titles of articles, reports and books written by Professor Winslow during the past fifty years. Highlight of the dinner was the announcement of the Winslow Public Health Seminar Fund, which will provide for prominent visiting lecturers and leaders of public health seminars.

GEORGIA

Dr. Richardson Named Chairman of Pharmacology Department.—Dr. Arthur P. Richardson, Memphis, Tenn., has accepted appointment as professor of pharmacology and chairman of the department at Emory University School of Medicine, Atlanta, effective July 1. Dr. Richardson has been associated with the Squibb Institute for Medical Research. He is a graduate of Stanford University School of Medicine, Stanford University-San Francisco, 1937, where he was assistant professor of pharmacology; later he was associate professor of pharmacology at the University of Tennessee College of Medicine, Memphis.

ILLINOIS

Study of Septic Tanks.—Suburban Cook County has been selected by the U. S. Public Health Service as one of three areas for a study of household septic tank disposal systems. Cook County was chosen as representative of the northern area of the country in the variety of tanks in operation and because of an organized source of records in the county health unit. The government hopes to develop standards whereby sludge capacity will be increased.

Chicago

Death of Mr. Halling.—Mr. Bliss O. Halling, acting director of the Bureau of Investigation at the headquarters of the American Medical Association, was found dead in his apartment July 2 of a heart attack. Mr. Halling was born in Iowa, Sept. 8, 1886. He was a veteran of World War I and had been on the staff of the Bureau of Investigation for about thirty years.

Society News.—At the annual meeting of the Chicago Gynecological Society June 20 Dr. Aaron E. Kanter became president, Dr. Herbert E. Schmitz president-elect and Dr. Edward M. Dorr secretary.——At the annual meeting of the Chicago Urological Society May 22 Dr. Irving J. Shapiro was elected president and Dr. James W. Merricks secretary-treasurer.——The Chicago Society of Internal Medicine at its meeting May 26 elected Dr. Henry T. Ricketts president and Dr. Ernest G. McEwen secretary-treasurer.

Dr. Hughes Heads Department of Ophthalmology.—Dr. William F. Hughes Jr., associate professor of ophthalmology, Indiana University School of Medicine, Bloomington-Indianapolis, has been named head of the department of ophthalmology at the University of Illinois College of Medicine, beginning July 2. Dr. Hughes graduated in medicine at Johns Hopkins University School of Medicine, Baltimore, in 1938, interned at Johns Hopkins Hospital and later served as assistant resident and resident ophthalmologist of the outpatient department. During the war he conducted research on treatment of chemical burns of the eye at Johns Hopkins University for the Office of Scientific Research and Development. He is a member of the American Academy of Ophthalmology and Otolaryngology and the Association for Research in Ophthalmology.

De Lee Professorship Established.—The Joseph Bolivar De Lee professorship of obstetrics has been established at the University of Chicago Medical School under an endowment fund set up by the Mothers' Aid of Chicago Lying-In Hospital and Dispensary, and Dr. M. Edward Davis, professor of obstetrics has been appointed to the chair. Dr. Davis, a graduate of Rush Medical College in 1923, became associated with Dr. De Lee as assistant resident of the hospital in 1925. He received the Gold Medal Award of the American Medical Association for studies in ergot in 1935, and the annual award of the Central Association of Obstetrics and Gynecologists in 1937 on the production of artificial ovulation. The De Lee professorship endowment is in honor of the founder of the Chicago Lying-In Hospital and Dispensary. Dr. De Lee first established a dispensary and home delivery service at Maxwell Street and Newberry Avenue in 1895.

LOUISIANA

State Medical Election.—At the annual meeting of the Louisiana State Medical Society in May Dr. Gilbert C. Anderson, New Orleans, became president and Dr. Marion D. Hargrove, Shreveport, president-elect; Dr. Paul T. Talbot was reelected secretary-treasurer for a five year term. The vice presidents are Dr. Philip H. Jones Jr., New Orleans, Arthur D. Long Jr., Baton Rouge, and Charles B. Odom, New Orleans. The next meeting of the society will be held in Monroe, La.

MICHIGAN

Faculty Honors Dr. Buesser.—A life size portrait of Dr. Frederick G. Buesser, professor of clinical medicine at Wayne University College of Medicine, Detroit, was presented to the university May 28 by the faculty. Dr. Buesser has been associated with the university for many years. The portrait will be placed in the auditorium of the medical school next to the portraits of Drs. William J. Stapleton Jr., Walter H. MacCracken, William A. Donald and Andrew P. Biddle.

Ragweed Pollen Count.—The seventh annual ragweed pollen survey will be conducted by the Michigan Department of Health beginning July 1 and continuing through September 15. Pollen counts for twenty-four hour periods from forty-eight places in the state will be furnished the public by newspapers and radio. Five areas, those surrounding Gaylord, Mackinaw City, Newberry, Rogers City and St. Ignace, had no ragweed pollen season last year, while Alpena, Charlevoix and Sault Ste. Marie had a one day season when the pollen counts exceeded 100 grains per cubic yard of air. The highest count came last year between August 26 and September 15. Grand Rapids had the longest season, twenty-seven days.

NEW YORK

Half of Centennial Fund for the Medical School.—One half of the centennial fund quota of $3,000,000 of the University of Buffalo will be used for the critical needs of the university's medical school—$500,000 for a new building and $1,000,000 for endowment. The medical dental building, to cost about $1,000,000, is 50 per cent financed by a gift from Mrs. Jessica Anthony Sherman and the bequest of Dr. DeWitt Halsey Sherman. The building is to house larger laboratories for instruction and research, an adequate library and medical museums. The endowment will be used principally for improvement and extension of teaching and research programs. Chairman of the medical division of the centennial fund campaign is Dr. William J. Orr, who is assisted by Drs. Matthew L. Carden, Henry N. Kenwell, John H. Talbott, Stuart L. Vaughan and Edward G. Winkler, all of Buffalo.

Personal.—At a drawing June 13 in Atlantic City Dr. Cyrus H. Maxwell, Albany, won the new Cadillac club coupe donated for the Centennial of the American Medical Association by White Laboratories, Inc., pharmaceutical manufacturers.——Dr. Irwin P. Sobel, associate pediatrician of Lenox Hill Hospital, has been appointed assistant clinical professor of pediatrics at the New York University College of Medicine. Dr. Sobel, a graduate of Columbia University College of Physicians and Surgeons, New York, served as lieutenant colonel in the medical corps during World War II.——Dr. George Draper, New York, has been appointed medical director of the Winifred Masterson Burke Relief Foundation convalescent home at White Plains, succeeding Dr. Lewis A. Conner. Dr. Draper, formerly associate professor of clinical medicine, Columbia University College of Physicians and Surgeons, has been engaged in special studies at the New York Hospital Cornell Medical Center.——Dr. Alfred J. Vignec has been appointed director of pediatrics at St. Vincent's Hospital, New York.

New York City

Child Health Center.—The department of health opened a child health center at the Manhattan Beach veterans' housing project June 25. It will serve about 1,100 families. The first of a series of nine similar centers, it will be staffed by a doctor and several nurses and will give health supervision and guidance on child growth and development of children from birth to 6 years of age.

Research on Cerebral Palsy.—A joint committee for research in problems of cerebral palsy has been established by the New York City, Bellevue and Presbyterian hospitals, the city health department, Cornell University Medical College, Columbia University College of Physicians and Surgeons and the New York University College of Medicine. Its purpose is to conduct research; intensify the development of diagnostic procedures and study the best way to organize, finance and operate clinics. Committee officers are Dr. Philip D. Wilson chairman and Dr. William Cooper secretary.

Rockefeller Institute to Consolidate Activities in New York City.—In view of the far reaching economic changes which have taken place in this country during the last two decades followed by the upheaval resulting from World War II, the trustees and scientific directors of the Rockefeller Institute for Medical Research are unanimous in the belief that the broad purposes for which the institute was founded can best be served and all phases of its activities strengthened by consolidating the institute's complete program on its York Avenue site in New York City. In spite of the increased cost of doing so, the prewar activities of the institute are to be resumed and continued in such a way as always to attract the best men by offering them the best conditions of work and the best facilities for it. The trustees at a meeting June 11 approved the integration in New York of the department of animal and plant pathology with the departments of the laboratories and the hospital, and authorized the necessary steps to be taken at the earliest practical date, but in no case later than July 1, 1951. The plan is to transfer to the New York plant all those activities of the institute at Princeton which can be transferred; then to make new arrangements for such other activities as may be continued. The president, John D. Rockefeller Jr., appointed a committee of four trustees to formulate and take the action required to carry out the purposes of the aforementioned resolution: Dr. Herbert S. Gasser, chairman, Mr. Barklie Henry and Mr. David Rockefeller with Lindsley F. Kimball, Ph.D., as an alternate to act in the absence of either Mr. Henry or Mr. Rockefeller.

OHIO

Fifteen New Research Contracts.—The Ohio State University Research Foundation announced the signing of contracts amounting to $428,171 for scientific studies to be conducted at the university for government agencies and industrial firms. James S. Owens, Ph.D., executive director of the foundation, reported that ten projects totaling $320,341 will be carried out for the Army Air Force, the Office of Naval Research, the Cleveland Ordnance District and the Army Engineer Board, Fort Belvoir, Virginia. Research contracts for five industrial firms total $107,830. Funds received by the research foundation go to pay the cost of the projects. The research foundation was incorporated in 1936 as a nonprofit organization to broaden the Ohio state research program and to correlate it with industrial and governmental interests. It not only supervises scientific investigations but it trains and develops personnel to further this work. Research covering a wide range of advanced developments is now being conducted in twenty-five departments of the university under contracts.

OKLAHOMA

Dr. Moorman Honored.—Dr. Lewis J. Moorman, Oklahoma City, one of the founders and for the last twenty-nine years president of the Oklahoma County Health Association, has been made "honorary president for life" of that organization. He assisted in the organization of the Oklahoma City Tuberculosis Society and was its first president in 1918. Since that time the society has expanded its activities and in 1939 became known as the Oklahoma County Tuberculosis and Health Association. Dr. Moorman is also editor of the *Journal of the Oklahoma State Medical Association*, served as dean of the University of Oklahoma School of Medicine 1931-1935 and is past president of the National Tuberculosis Association, the American Trudeau Society and the Southern Medical Association.

OREGON

Professor Livingston Returns to Oregon.—Dr. William K. Livingston, guest professor in the department of anatomy, New York University College of Medicine, New York, will become professor of surgery and head of the department at the University of Oregon Medical School, Portland, August 1. Dr. Livingston is a graduate of Harvard Medical School, Boston, 1920, and is a former member of the University of Oregon Medical School faculty. Prior to assuming his new position Dr. Livingston is to be a guest speaker at the Association of Surgeons of Great Britain and Ireland during its sessions in Oxford and will also deliver departmental lectures at Oxford University.

PENNSYLVANIA

Seventh Rheumatic Heart Clinic.—The seventh rheumatic heart clinic of the state health department was opened in April at Wilkes-Barre General Hospital with Dr. John F. Giering, Kingston, as director. No treatment will be given at the clinic, but patients registered will be diagnosed and recommendations for treatment will be sent to patients' physicians. Dr. Giering is a graduate of the University of Scranton and the Jefferson Medical College of Philadelphia. Other rheumatic heart clinics established by the state under the program of the 1945 general assembly are located in Erie, Harrisburg, Altoona, Williamsport, Allentown and Sayre.

Army Officer Appointed Director at Mont Alto.—Brigadier General Henry C. Dooling, U. S. Army, Retired, has been appointed medical director of the Pennsylvania State Sanatorium No. 1 (Mont Alto), South Mountain. A graduate of Medico-Chirurgical College of Philadelphia, 1908, Dr. Dooling practiced medicine in Norwood for seven years before entering the U. S. Army in 1917. During the late war he served as chief health officer in the Panama Canal Zone and directed the activities of six hospitals. He succeeds Dr. Charles C. Custer, retired. The sanatorium, with a total capacity of 1,700 beds, is the oldest and largest of the three state institutions for the care and treatment of tuberculosis victims who cannot afford private hospitalization.

Philadelphia

Society News.—The Philadelphia Psychoanalytic Society elected the following officers at its meeting June 14: Dr. LeRoy M. A. Maeder, Philadelphia, president and Dr. Robert S. Bookhammer, Philadelphia, secretary-treasurer.

Woman's Medical College Honors Seven Graduates.—At commencement exercises of the Woman's Medical College of Philadelphia on June 6 special citations were presented to seven members of the class of 1897 on the fiftieth anniversary of their graduation. The doctors are Louise B. Healy, Lexington, Ky.; Sylvia B. Martin, Landing, N. J.; Clara P. Fitzgerald, Worcester, Mass.; Edith Flower-Wheeler, Cortland, N. Y.; Martha G. K. Schetky, Philadelphia; Agnes Sholly-Knights, Selinsgrove, Pa., and Rosalie Slaughter-Morton, Winter Park, Fla.

SOUTH CAROLINA

State Medical Election.—At the annual meeting of the South Carolina Medical Association early in May Dr. Olin B. Chamberlain, Charleston, was made president; Dr. Clough H. Blake, Greenwood, vice president; Dr. Robert B. Durham, Columbia, president-elect, and Dr. Julian P. Price, Florence, secretary-treasurer.

Health Commissioner of Greenville.—Dr. Clarence L. Guyton, Columbia, has resigned as director of the state board of health division of venereal disease and cancer control and accepted the appointment of city health commissioner at Greenville. A graduate of the Medical College of South Carolina, Charleston, Dr. Guyton organized and developed the state's cancer control program.

VIRGINIA

Retired Navy Officer Becomes Health Officer.—Dr. Richard B. Blackwell, who has assumed the duties of health officer of Rockbridge County, succeeds Dr. Robert P. Cooke, who retired after serving twenty years as health officer. Dr. Blackwell recently retired from the navy after thirty years of service.

WEST VIRGINIA

Public Health Association.—At the annual meeting of the West Virginia Public Health Association at Clarksburg, May 16-17, the following officers were elected: Dr. Leon A. Dickerson, Madison, president; Mr. A. L. Lively, Bluefield, and Charlotte McLaughlin, Charleston, vice presidents, and Annette King, Charleston, secretary-treasurer. Mr. C. E. Bright, Romney, Dr. Thomas C. Sims, Fayetteville, and Mrs. Mary Jane Stienspring, West Union, were elected members of the executive board.

New Health Center Dedicated.—The new health center at Lewisburg was dedicated June 9. The headquarters for Health District No. 2 are located in the health center, which for years has been known as the "John A. Preston Community House," use of which was offered by the city's Women's Club. Mr. C. K. Swinell, White Sulphur Springs, presented the health center with laboratory equipment. As soon as additional equipment and personnel are available, the state health department will establish in the center West Virginia's first branch laboratory to the state hygienic laboratory. The state plans are to make this health unit a postgraduate training center in pediatrics for doctors in the state who wish to avail themselves of the knowledge of modern diagnostic methods in pediatrics.

PUERTO RICO

Tuberculosis in Puerto Rico.—Administrative control of the five tuberculosis hospitals was transferred from the Division of Public Health to the newly created Division of Hospitals during 1945. Tuberculosis, like malaria, is still one of the leading causes of death in Puerto Rico, although its incidence is decreasing. Case and death rates for 1945 were 281.6 and 202.2 per 100,000 inhabitants, respectively, compared with rates of 332.9 in 1944 and 215.4 in 1943. A total of 104,934 persons was examined in the 20 tuberculosis clinics, 128,752 persons were fluoroscoped, 16,602 chest x-rays were made. New cases discovered totaled 4,163. Pneumothorax treatment was given to 9,204 patients and 46,831 were given pneumothorax insufflations.

GENERAL

Committee of Revision of Pharmacopeia.—Following the resignations of C. Leonard O'Connell, E. E. Nelson and A. B. Lemon from the U. S. P. Revision Committee, Mr. John J. Dugan, New Haven, Conn., Frederick F. Johnson, Ph.D., Berkeley, Calif., and Dr. Austin E. Smith, Chicago, have been elected to fill the respective vacancies.

Allergy Academy Issues Directory.—The American Academy of Allergy has issued an alphabetical and geographic directory of its fellows and members. A biographic sketch of each physician is included. Copies may be secured on request to Dr. Theodore L. Squier, Secretary, the American Academy of Allergy, 424 East Wisconsin Avenue, Milwaukee 2.

Narcotic Violations.—The following physicians recently pleaded guilty at Atlanta, Ga., and Brooklyn, respectively, to violations of the Federal Narcotic Law and have been sentenced as follows: Dr. William R. Richards, Greensboro, Ga., eighteen months, and Dr. Paul V. Conboy, 842 Park Place, Brooklyn (placed on probation on March 27 for a period of five years).

Traffic Deaths in May.—The National Safety Council, Chicago, reports that traffic deaths in the United States for May 1947 totaled 2,710, an increase of 6 per cent over May of last year. For the first five months of this year the grand total was 11,990 deaths, a reduction of 11 per cent for the same period in 1946. Of 371 cities reporting, 236 had perfect records for May, the largest one being Providence, R. I., the second Salt Lake City and the third Wichita, Kan. For the five month period 111 cities had perfect records, the largest being Schenectady, N. Y., the second New Britain, Conn., and the third Evanston, Ill.

Gastroenterologic Award.—The National Gastroenterological Association has awarded Dr. Frederick Duran-Jorda, Manchester, England, its 1947 prize of $100 and a certificate of merit for the best unpublished contribution on gastroenterology. Dr. Duran-Jorda's paper on "Histopathology of the Semisquamous Epithelial Layer as Found in the Colon" was selected from twelve entries received from all parts of the world. The award was presented at the annual banquet of the association, Atlantic City, N. J., June 5 together with certificates of merit given to Drs. William Nimeh, Mexico City, D. F.; August Schrumpf and Trygve Kahrs, Porsgrunn, Norway; W. Paolino and G. Boccuzzix, Turin, Italy.

Aid for Child Spastics.—The sum of $250,000 is being set aside by the Children's Bureau, Department of Labor, for the development in 1948 of a program to aid juvenile victims of cerebral palsy. New York State will receive $50,000 from the Children's Bureau to train personnel in the technics of treating spastics to augment state appropriations of $25,000. Maryland and Alabama will also receive $50,000 grants and New Jersey $30,000. About thirteen states which have made a beginning in this field will receive small amounts from federal funds. The bureau estimates that there are in this country about 175,000 children with cerebral palsy.

Board of Ophthalmology Replaces Personal Interview.—At the last meeting of the American Board of Ophthalmology it was decided to replace the personal preliminary interview with a written qualifying test for all applicants. This is, in part, to save them the expense and time in traveling long distances when national meetings are held. The written test, therefore, will be held simultaneously in many parts of the country on Wednesday, July 23, at 1 p. m., and again during the winter, 1947-1948. Candidates then qualifying will be admitted to the practical examination. Registration for Chicago (limited to 60 candidates), October 7-12, has been closed.

Remington Medal Awarded.—The 1947 Remington Medal has been awarded Dr. Rufus A. Lyman, retiring dean of the University of Nebraska College of Pharmacy. The award, made by the New York Branch of the American Pharmaceutical Association, will be presented this fall. The honor is conferred on the person whose work is judged most important to American pharmacy by a committee of past presidents of the association. Dr. Lyman's advice and guidance have been sought in the councils of pharmaceutical educators for nearly four decades. In 1937 he founded and continues to edit the *American Journal of Pharmaceutical Education*. He took his medical degree at the University of Nebraska College of Medicine, Lincoln, practiced for a time in Omaha and then became professor of pharmacology at his alma mater. He was chosen director of the School of Pharmacy when it was established in 1908 and has only recently retired.

Tuberculosis Delegates to International Meeting.—The National Tuberculosis Association will be represented by five delegates at the meeting of the council of the International Union Against Tuberculosis in Paris, France, July 28 to 29.

The delegates are Drs. Kendall Emerson, New York managing director of the association, Esmond R. Long, Philadelphia, director for the division of research, H. Corwin Henshaw, vice president, Herman E. Hilleboe, Washington, D. C., assistant surgeon general, U. S. Public Health Service and member of the board of directors, and Mr. F. D. Hopkins, executive secretary. The council will discuss reorganization of the International Union Against Tuberculosis. In addition to those named to attend the Paris meeting, the National Tuberculosis Association's representatives on the council include Drs. J. Burns Amberson, Waynesboro, Pa., James R. Reuling, Bayside, N. Y., president-elect, and Herbert R. Edwards, New York, secretary.

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the periods indicated have been received from the division of public health methods, U. S. Public Health Service:

A New Medical Periodical.—The College of Medical Evangelists in Los Angeles has begun publication of a quarterly to be known as *Medical Arts and Sciences.* The periodical will contain articles which pertain to the practical, cultural, philosophical, experimental, investigative and critical sides of medicine. The leading article in the first issue, by Arthur L. Bietz, Ph.D., entitled "Religion and Health," is followed by an article in the field of surgery by Dr. Harry A. Davis, associate professor of surgery, College of Medical Evangelists, Los Angeles, one on cerebral anoxia by Dr. Cyril B. Courville, Rumford, Maine, and another on intracranial surgery by Dr. William T. Grant, Los Angeles. The editor in chief is Dr. Walter E. MacPherson, Los Angeles, and the managing editor Dr. Clarence W. Olsen, 312 North Boyle Avenue, Los Angeles. Matters pertaining to advertising should be sent to C. R. MacIvor, Review and Herald Publishing Association, Takoma Park, Washington, D. C.

Special Society Elections.—At April meetings the following societies elected officers: The American Association for the Study of Goiter chose Dr. James H. Means, Boston, president; Dr. Arnold S. Jackson, Madison, Wis., president-elect; Dr. Thomas C. Davison, Atlanta, Ga., secretary.——The American Otological Society, Inc., elected Dr. Bernard J. McMahon, St. Louis, president and Dr. Marvin F. Jones, New York, secretary.——The American Laryngological Association elected Drs. Arthus W. Proetz, St. Louis, president and Louis H. Clerf, Philadelphia, secretary.——At meetings in May the following elected officers: American Association of Pathologists and Bacteriologists, Drs. Malcolm H. Soule, Ann Arbor, Mich., president; Ernest W. Goodpasture, Nashville, Tenn., president-elect, and Howard T. Karsner, Cleveland, secretary.——The American Pediatric Society named Dr. Grover F. Powers, New Haven, Conn., president; Dr. Harold B. Cushing, Montreal, Que., president-elect, and Dr. Henry G. Poncher, Chicago, secretary.——The American Society for Experimental Pathology chose Drs. Douglas H. Sprunt, Memphis, Tenn., president, and Frieda S. Robscheit-Robbins, secretary.——The American Society for Pharmacology and Experimental Therapeutics elected Dr. Maurice H. Seevers, Ann Arbor, Mich., president, and Dr. Harvey B. Haag, Richmond, Va., secretary.——The Association of American Physicians elected Dr. Alvah H. Gordon, Montreal, Que., president, and Dr. Henry M. Thomas Jr., Baltimore, Md., secretary.

CORRECTIONS

Proceedings of the Atlantic City Session.—In the Proceedings of the Atlantic City Session in The Journal, June 28, page 804, second column, line 7, the words "Board of Trustees" should be substituted for the words "House of Delegates."

Vitamin D ("Ertron") Therapy in Arthritis.—In the article by Drs. Paul Kaufman, R. Donald Beck and Richard D. Wiseman on "Vitamin D ('Ertron') Therapy in Arthritis" in The Journal, June 21, 1947, page 690, lines 5 and 8, a decimal point was omitted from the blood calcium figures. They should read 14.7 mg. and 13.0 mg., respectively, rather than 147 mg. and 130 mg. per hundred cubic centimeters.

Iodine Deficiency in Goiter.—Dr. Isidor Greenwald, New York, referring to the editorial on this subject published in The Journal March 1, points out that the release made by Science Service was based on an article in the *Journal of Clinical Endocrinology* **6**:708 and an article in another publication, the *Bulletin of the History of Medicine* **17**:229, 1945. He cites these articles as evidence in support of his contention that deficiency of iodine is not related to the development of simple goiter.

Marriages

Rudy E. Ruark, Uniontown, Ky., to Miss Ruth Etoile Burkhalter of Winchester, Tenn., in Rossville, Ga., March 9.

Thomas William Quinn, Napoleon, Ohio, to Miss Annamae Joanne Maloney of Dunmore, Pa., July 27, 1946.

George W. Bounds Jr., Meridian, Miss., to Miss Doris Jean Condit of Neoga, Ill., in Iowa City March 9.

Claudius A. Clements, Daisy, Tenn., to Miss Gladys-Dean Stewart of Chattanooga, Oct. 27, 1946.

Walter Henry Patt Jr., St. Joseph, Mo., to Miss Frances Swinney of Harrisburg, Ill., recently.

George Dail Penick to Miss Marguerite Murchison Worth, both of Raleigh, N. C., February 8.

Clarence D. Barrett Sr., Dearborn, Mich., to Mrs. Edith M. Wyatt of Leslie Dec. 30, 1946.

Edward N. Stevenson to Miss Fredrika Moore Sasser, both of Memphis, Tenn., January 15.

Frank B. Snell, Baltimore, to Miss Virginia Lee Gregson in Sanford, N. C., January 4.

Deaths

Edward Coleman Ellett ⊕ Memphis, Tenn.; born in Memphis, Tenn., Dec. 18, 1869; University of Pennsylvania Department of Medicine, Philadelphia, 1891; served as the resident physician at St. Agnes Hospital and as house surgeon at Wills Eye Hospital, both in Philadelphia; in 1893 returned to Memphis, where he had been professor of opthalmology at the University of Tennessee College of Medicine from 1908 to 1922; secretary of the Section on Ophthalmology of the American Medical Association 1900-1901 and chairman of the section 1914-1915; past president of the American Ophthalmological Association, Memphis and Shelby County Medical Society and the Tennessee Academy of Ophthalmology and Otolaryngology; served as vice president of the Southern Medical Association; member of the Association for Research in Ophthalmology; fellow of the American College of Surgeons; in October 1942 given the Award of Merit of the American Academy of Ophthalmology and Otolaryngology in recognition of his services as president and member of the council; vice president and for many years a member of the board of directors of the National Society for the Prevention of Blindness; in 1939 in cooperation with the St. Louis Society for the Blind awarded the Leslie Dana Medal; member of the original American Board for Ophthalmic Examinations which later became the American Board of Ophthalmology, serving as consultant and at one time as its president; commanding officer of Base Hospital 115 in France with the rank of lieutenant colonel during World War I and received a citation for "exceptionally meritorious and conspicuous service"; discharged as a colonel in the medical corps of the U. S. Army Reserve; chief of staff of the Memphis Eye, Ear, Nose and Throat Hospital and on the staff of the Methodist Hospital; author of a chapter on "Disease of the Lacrimal Apparatus" in Berens's textbook The Eye and Its Diseases; received honorary degrees from the Southwestern College and the University of the South in Sewanee, Tenn.; died June 8, in Atlantic City while attending the annual session of the American Medical Association, aged 77, of coronary thrombosis.

William Emmet Gardner ⊕ Louisville, Ky.; born in Sonora, Ky., Aug. 24, 1877; University of Louisville Medical Department, 1902; professor of psychiatry at his alma mater; specialist certified by American Board of Psychiatry and Neurology; fellow of the American College of Physicians; member of the Southern Psychiatric Association, Kentucky Psychiatric Society and the American Psychiatric Association; formerly councilor of the Fifth District, president and vice president of the Kentucky State Medical Association; past president of the Jefferson County Medical Society and the Louisville Society for Mental Hygiene; affiliated with the Louisville Neuropathic Sanatorium; at one time superintendent of the Central State Hospital in Lakeland; member of the visiting staffs of the General Hospital, Norton Memorial Infirmary, St. Joseph Infirmary and Kentucky Baptist Hospital; lieutenant commander in the medical corps of the U. S. Naval Reserve; died April 8, aged 69, of coronary heart disease.

Malvern Bryan Clopton ⊕ Wianno, Cape Cod, Mass.; University of Virginia Department of Medicine, Charlottesville, 1897; served as president and member of the board of directors of Washington University Corporation and as professor of clinical surgery at the Washington University School of Medicine in St. Louis, where he had been on the staffs of the Barnes, St. Luke's, St. Louis Children's and the Jewish hospitals; served as president of the state board of health of Missouri and the Missouri Association of Occupational Therapy; member of the American Surgical Association, Southern Surgical Association, Western Surgical Association and the Society of Clinical Surgery; fellow of the American College of Surgeons; member of the founders group of the American Board of Surgery; served in France during World War I; died April 21, aged 71, of cerebral arteriosclerosis.

David Adiger ⊕ New Orleans; Tulane University of Louisiana School of Medicine, New Orleans, 1913; served overseas during World War I; on the staffs of the Southern Baptist and Charity hospitals; died April 2, aged 57, of coronary thrombosis.

Merlin Zeno Albro, Chicago; College of Physicians and Surgeons, medical department of Columbia College, New York, 1887; formerly secretary of the Chicago Medical Society; died in the Wesley Memorial Hospital April 24, aged 81, of arteriosclerotic heart disease and cerebral vascular sclerosis.

Fred McKinley Bantum, Cumberland, Ohio; Eclectic Medical Institute, Cincinnati, 1918; died March 28, aged 52, of coronary thrombosis.

Frank Asahel Burnham ⊕ Arnold, Neb.; University of Nebraska College of Medicine, Omaha, 1911; past president of the Custer County Medical Society; for many years served on the board of education and the library board; died April 6, aged 69, of cardiorenal disease.

Herman S. Ehrenreich, St. Louis; St. Louis College of Physicians and Surgeons, 1906; served during World War I; major, medical reserve corps, not on active duty; died March 31, aged 68, of coronary thrombosis.

Otis W. Fesmire, Atwood, Tenn.; University of Tennessee Medical Department, Nashville, 1905; member of the American Medical Association; formerly a druggist; past president of the Carroll County Medical Association; died March 31, aged 71, of heart disease.

William Henry Hurley ⊕ Northfield, Vt.; Maryland Medical College, Baltimore, 1903; served during World War I; died April 26, aged 69, of coronary thrombosis.

Charles Michael Kent, Kenedy, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1915; member of the American Medical Association; past president of the Karnes-Wilson Counties Medical Society; served during World War I; formerly owner of the Kenedy Clinic and Hospital; died February 28, aged 58, of cerebral hemorrhage.

David Isaac Nalitt ⊕ Bayonne, N. J.; Baltimore Medical College, 1901; vice president and president-elect of the Hudson County Medical Society; past president of the Bayonne Medical Society; examining physician for the Selective Service in Hudson County for many years; on the staff of the Greenville Hospital in Jersey City and on the staff of the Bayonne Hospital, where he died April 4, aged 68, of coronary occlusion.

William Charles Ohlendorf, Park Ridge, Ill.; Chicago Medical College, 1882; died March 17, aged 89, of myocarditis and diabetes mellitus.

Justus Edgar Olsson, Lexington, Neb.; University of Nebraska College of Medicine, Omaha, 1910; served overseas during World War I; on the staff of the Community Hospital; died March 22, aged 63, of cerebral hemorrhage.

Louis Edward Penner, Beatrice, Neb.; University of Nebraska College of Medicine, Omaha, 1904; member of the American Medical Association; on the staffs of the Lutheran Hospital and the Mennonite Hospital, where he died March 25, aged 72, of carcinoma of the lung.

Robert E. Lee Ringo, West Palm Beach, Fla.; University of Louisville (Ky.) Medical Department, 1898; died February 23, aged 74.

Frank Fishel Sandler ⊕ Revere, Mass.; Tufts College Medical School, Boston, 1915; member of the American Society of Anesthetists; served during World War I; chairman of the board of health; died March 24, aged 55.

James Guy Van Scoyoc ⊕ Los Angeles; John A. Creighton Medical College, Omaha, 1914; also a graduate in pharmacy; assistant clinical professor of medicine at the University of Southern California School of Medicine; formerly on the faculty of the University of Utah School of Medicine, Salt Lake City; served during World War I; on the staff of St. Vincent's Hospital; died March 23, aged 56, of cerebral vascular accident.

Walter Levi Slifer, Philadelphia; Jefferson Medical College of Philadelphia, 1903; died February 20, aged 65.

Homer Hinton Tallman ⊕ Culver, Ind.; Northwestern University Medical School, Chicago, 1900; served during World War I; major, medical reserve corps, U. S. Army, not on active duty; member of the chamber of commerce and the Lions Club; affiliated with the Parkview Hospital in Plymouth and the Kelly Hospital in Argos, where he died March 29, aged 73, of hypostatic pneumonia.

Ralph Waldo Wakefield ⊕ Bar Harbor, Maine; Jefferson Medical College of Philadelphia, 1902; past president of the Maine Medical Association and the Hancock County Medical Society; member of the New England Surgical Society; fellow of the American College of Surgeons; president of the Bar Harbor Banking and Trust Company; on the staff of the Mount Desert Island Hospital; died March 31, aged 69, of coronary thrombosis.

Magdalena Wambsganss, Newark, N. J.; George Washington University School of Medicine, Washington, D. C., 1917; member of the American Medical Association; on the staff of the Lutheran Hospital, where he died March 28, aged 64, of heart failure following a cholecystectomy.

William Clyde West ⊕ Alexandria, Va.; Medical College of Virginia, Richmond, 1920; served during World War I; past president of the Alexandria City Medical Society; formerly health officer; died April 1, aged 54.

A New Survey of the Prevalence of Illness

A new survey of the prevalence of illness has been introduced. Sir William Jameson, chief medical officer of the Ministry of Health, states that it provides basic information of great value in adjusting the health services to the needs of the community and "in assaying the progress of our work" Until recently the only illnesses on which there were definite figures were the compulsorily notifiable diseases. There were also of course the national insurance records, but these dealt with only part of the population and with illness causing incapacity for four or more days. There was no nationwide measurement of the amount of general illness or of the incapacity resulting from it. To supply this the government has during the last three years been conducting by a social survey organization which it uses for various purposes a continuous survey of the prevalence of illness. The method adopted is a sampling inquiry from which conclusions can be drawn as to the whole population. The work is done by trained interviewers, mostly women. About 3,000 people are chosen at random every month, each time in a different district. The interviewers ask them questions about their health, housing conditions, occupation and income. The survey is voluntary and confidential, and only 0.5 per cent of those interviewed have declined to take part The replies are collected and dealt with by medical statisticians.

Among the facts brought to light the following are the most important: In England and Wales the annual loss of men's work through illness is about 250 million man-days. In 1945 1 out of every 5 people had a cold in January, 1 out of 20 in July. Women complain of about 25 per cent more minor ailments than men, but for defined illness of a more serious nature there is little difference between them. The amount of new illness does not increase as age advances. The rate at which people consulted their doctors in 1944 averaged about 6 attendances a head of the civil population over the age of 15. There were vast differences in the rates of incidence in various occupations. Illness occurs less frequently among those employed in mining and quarrying than in any other occupation, but injury more frequently. In distributive employment both illness and injury occur relatively seldom; but, on the whole, where illness is relatively frequent, injury is relatively rare, and vice versa. Residents in urban areas are not freer than rural dwellers from illnesses of any kind, but there are some to which they are particularly prone. In the whole sample the estimated average number of days' incapacity caused by all sickness was only 1.4 per person monthly in the winter months of 1944-1945.

The Nostrum Evil

The nostrum evil has often been denounced but it continues to flourish, as advertisements in the press and at railway stations and other public places show. The approaching national health service has produced apprehension of an increase of the evil. This may seem strange, as one would think that the provision of all kinds of medical treatment for which no payment will be made should diminish the demand for expensive nostrums. But the national health insurance act, which did on a smaller scale what the national health service is to do universally, was followed by an increased consumption of nostrums. The psychologic reason is simple. The British public is prone to think little of what can be obtained for nothing and believes that nostrums must be valuable because so expensive.

The Pharmaceutical Society is making a determined effort to check the nostrum evil. It has transmitted to the ministry of Health a memorandum based on a five year inquiry, which runs to 14,000 words. "Throughout the pages of most newspapers and periodicals in general circulation," says the report, "sufferers from all manner of diseases and ailments are offered beans, tablets, wines, powders, salts, pills, ointments, tonics, hormones, glands and vaccines that will bring them youth, health, charm, slimness, inner cleanliness, lively livers, increased (or decreased) weight, iron for the blood, purer blood, vitamins, contentment, resolution, immunization." Nostrums are advertised in terms which tend to make the public conscious of diseases, to regard ill health as the normal condition, encourage self medication as a habit and postpone the seeking of skilled advice. The advertising of nostrums is so extensive that the influence of advertisers prevents the ventilation of reforms in the press. The society urges that the sale of unregistered medicines should be prohibited and that standards for medicines and for advertisments should be prescribed. For this work the government should be assisted by an advisory committee of physicians and pharmacists. The nostrum venders have an association which has attempted a reply in the press to these accusations. It alleges that the censorship work of their association and of the Newspaper Proprietors Association has "practically eliminated all undesirable forms of advertising" In the light of the findings of the Pharmaceutical Society that word "practically" can be regarded as only an admission which falls far short of the reality.

A Death from Pethidine

The first case of death from the new analgesic pethidine has been observed in London. A clerk aged 44 was found unconscious in a hotel and died soon afterward. Four bottles of ¾ grain tablets of pethidine, from which fifty-four were missing, were found in his room. At the inquest Dr. G. Roche Lynch, toxicologist, gave evidence that this was the first case of pethidine poisoning that he had met. The drug is described as the hydrocloride of the ethyl ester of 1-methyl 4-phenylpiperidine 4-carboxylic acid.

Unprecedented Number of Births

The National Service of Statistics has published figures of the movements of the population in France for the first half of 1946. The number of living births was 428,261 as against 313,630 in 1945 and 311,677 in 1939 for the same period The total figure covering deaths was for the first six months of 1946 305,226 as against 356,918 in 1945 and 350,076 in 1939 These figures show an excess of births of 123,035 for the first half-year of 1946 instead of an excess of deaths amounting to 33,288 for the same period of 1945 and of 37,399 for 1939. It is the first time in eleven years that France has had such an excess of births, and it is, moreover, of an unprecedented magnitude There were 244,990 marriages during the first half-year of 1946 as against 135,028 and 124,034 for the same period of 1945 and 1939 respectively. An increase of divorces for the first half-year of 1946 is to be noted; they amount to 21,159 as against 10,166 and 11,900 for the same periods of 1945 and 1939 respectively; this is due to postwar conditions and also to the accumulation of delayed registering. As regards the death rate of children under 1 year of age, the situation has improved in comparison with 1945. The death rate for 1946 works out at 67 per thousand children born alive as against 108 per thousand for 1945. This diminution is due to the amelioration of the sanitary conditions and to legislation concerning the maternity and infantile protection; this death rate remains nevertheless higher than the death rate of 1938, which was 66 per thousand of children born alive

Treatment of Multiple Osseous Metastasis with Radium

Up to the present, the radiotherapy of cancer has had its drawbacks and limits on account of the impossibility of using massive doses without incurring the risk of either destroying normal tissues or of producing anemia. Dr. P. Lehmann of the Bichat Hospital set forth before the Academy of Sciences in 1941 a new process for diminishing artificially the radiosensitivity of the skin and mucosa in roentgen therapy. The author used the following ointment, which is spread on the skin previously cleaned: epinephrine 0.01 Gm., stovaine 1 Gm., benzoinated hog fat 100 Gm. For the desensitization of the pharyngolarynx he uses glycerin as an excipient. He also presented to the Paris Society of Medicine the first results of this new method of radiotherapy of cancer, which enabled him to treble the usual dose of x-rays without manifestation either immediate or belated of any radiolesion. At a recent meeting of the Academy of Surgery Dr. P. Lehmann presented 4 cases of multiple osseous metastasis of cancer of the breast selected from a large number which have been treated with massive doses of x-rays. A patient received in twenty-two months 55,000 roentgens through various fields and seventy-eight courses of total teleradiotherapy. Another had fifteen courses of total teleradiotherapy within six weeks and locally 6,000 roentgens; pains have disappeared, the general condition has improved rapidly and the examination of the blood disclosed a normal blood formula. After one year the patients are doing well. During the treatment the author saw a calcic reconstruction of the bones invaded by cancer, while neoplastic tissues are destroyed and disappear. There is not, therefore, a danger of spontaneous fracture, and it is not necessary to keep the patients laid up or to maintain them by means of an orthopedic corset. He has also found that by means of the combination of total teleradiotherapy and of local irradiations it is possible to treat in the same patient a series of concomitant metastases without determining by irradiation a new seat of evolutive outbreak elsewhere. It is interesting that the irradiated segment remains cicatrized and that no growth of cancer occurs there. Lehmann has observed that by massive doses of x-rays it is possible to bring to view, under the form of rounded opacity, latent metastases and to treat them precociously. At a meeting of the Society of Dermatology the same author, taking as a basis fifty observations of irradiated cancers, demonstrated the nonexistence of x-ray anemia so much dreaded up to now. The anemia in the irradiated cancerous patient, he said, is not due to radiotherapy but to the evolution of the disease. By not letting metastases develop, which has become possible thanks to the new Lehmann process, anemia regresses as from the third week of radiotherapy with massive doses. We are now in possession of a method permitting extension of the life of patients with multiple metastases.

Registering the Mode of Action of Antibiotics

Recent technical progress has permitted following in vitro, by photometric registering, the stages of the fight of drugs against microbes. Bonet-Maury and Walen's differential registering photometer registers simultaneously six curves of growth of bacterial cultures contained in special vials through which passes a luminous ray and which are constantly mechanically agitated. The apparatus works automatically, night and day, in a room kept at 37 C. At a meeting of the National Academy of Medicine Bonet-Maury, chief of service at the Fournier Institute, Paris, has set forth the results of research which demonstrates that each antibiotic has a distinctive curve. Sulfonamides have a checking action on staphylococci, without bactericidal action or lysis. Real bacteriostasis in vitro is obtained only by very high concentrations of sulfonamides, much superior to those realized in the organism in the course of a treatment. The action of a few hundred Oxford units of penicillin (dose much inferior to the one realized in the organism) is much more complex, either bactericidal, bacteriostatic, lytic or checking. While the action of a penicillin-sulfonamide mixture is synergic, it is penicillin which imposes its mode of action on the mixture. The action of streptomycin on Escherichia coli gives curves similar to the curves of penicillin on staphylococci, but with the latter, with a feeble dose a checking action without lysis is observed. Streptomycin requires doses about one thousand times higher than penicillin for stopping multiplication. This new method permits study of the modus of action of an antibiotic, which it has been impossible to check heretofore.

International Conferences in Copenhagen

The repeated choice of Copenhagen for the holding of international medical conferences suggests that this city enjoys a growing reputation as a medical center. From July 20 to 26 of this year the fourth International Congress of Microbiology is to be held in Copenhagen under the presidency of Denmark's Grand Old Man in medicine, Dr. T. Madsen, and the vice presidency of Professor S. Orla-Jensen. The first of the nine different sections will be directed by Professor K. A. Jensen, whose work on antibiotics is well known. Professor S. A. Waksman is among the Americans listed to speak on antibiotics. Between twenty and thirty papers will be presented in each section, a quarter of an hour being allotted to each paper. Another international congress to be held this year in Copenhagen is the first European Rheumatology Congress on September 4-8, over which Professor Cai Holten will preside. For further information on this subject apply to Rigsforeningen til Bekaempelse av Rheumatiske Sygdomme, Rysensteensgade 16, Copenhagen V.

The Treatment of Burns

For some forty years the treatment of burns in Copenhagen has been concentrated in the Rudolph Bergh Hospital. Between 1916 and 1935 the mortality was 7.1 per cent, being as low as 5.2 per cent in the latter part of this period, 1930-1934. Between 1938 and 1945 the annual mortality ranged from 2.1 to 4 per cent. How has this remarkable reduction in the mortality been achieved? In the opinion of Dr. A. Kristiansen of this hospital the main credit belongs to the greater attention paid to the patient's general condition, i. e. to the combating of shock. In the period under review fashions have changed in local treatment, not always for the better: witness the brief rise and sudden decline in the popularity of treatment with tannic acid, whose provocation of central necroses in the liver has led to its downfall. At present local treatment consists largely of antiseptic ointments on appropriate dressings, penicillin ointments being among the latest innovations. Another movement is toward closer cooperation between physicians and surgeons with a view to timely skin grafting. At the Rudolph Bergh Hospital Dr. Kristiansen often recommends the transfer of his patients to surgical care some three weeks after a burn. The paper which Dr. A. Zacho and Dr. A. Gammeltoft presented last year on the subject of burns at a meeting of the Danish Surgical Society included a plea for early skin grafting.

Rheumatic Fever and Hemolytic Streptococci

At Medical Department B of the Odense County and City Hospital, antistreptolysin titer tests are carried out as a routine measure in cases of rheumatic fever. Throughout 1943 and 1944 all the 127 rheumatic fever patients in this hospital were thus tested. Dr. Fritz Harving, who recently gave an account of this test at a medical meeting at Odense, pointed out that this titer was definitely raised in 81 per cent of his cases, and that in the remaining 19 per cent there were certain features distinguishing them from the majority. At any given moment the test is apt to be misleading, but a sustained comparison of its behavior with the clinical course of the disease reveals a correlation which is instructive; and when a high titer shows no tendency to fall, it is well to suspect that the disease is still active even when clinical evidence is suggestive of its arrest.

Penicillin Research in Denmark

The reports presented in 1946 at a meeting of the Danish Medical Society have been published in *Nordisk Medicin* for March 21 and give a good bird's eye view of the results of the systematic team work in this field undertaken by the Danes The bacteriologist Professor K A. Jensen has played a leading part Intramuscular injections given every third hour, are on the whole, preferred in Denmark to continuous intramuscular or intravenous injections, and at the Blegdam Fever Hospital penicillin is given with epinephrine by subcutaneous injections three times a day. At each of these three injections 100,000 units is given. The clamor by the public for penicillin treatment for every conceivable ill has, of course, become a veritable nuisance.

BRAZIL

(From Our Regular Correspondent)

São Paulo, May 27, 1947.

The Use of Leukotomy in Epilepsy

As soon as the cerebral leukotomy of Egas Moniz, Freeman and Watts was introduced in psychiatry as a method of treatment its application was extended to epilepsy with not very encouraging results Dr. Mário Yahn at the Hospital de Juquery, São Paulo, chose six chronic epileptic patients to study the effects of frontal and parietal leukotomy One patient with a psychopathic personality, misconduct, hysteria and epileptic fits fully recovered after the operation In 2 patients with infantile encephalopathy, hemiplegia and deviations of behavior, 1 greatly improved as to the number of seizures, without mental changes In the other the number of seizures was later reduced. Of 3 patients considered to have essential epilepsy with deviations of behavior, in 2 good results were obtained, although the third showed signs of aggravation The mental state of 1 patient was improved.

Dr. Mário Yahn believes that the verified improvements do not depend directly on the sectioned pathways but on a new postoperative integration Leukotomy cannot yet be used as a routine method of treatment for epilepsy'

Only chronic and very serious cases with frequent seizures and misconduct with whom other methods of therapy have failed should be treated by cerebral leukotomy.

Salmonella in Meat Products

Various types of meat products obtained from different butchers of São Paulo were examined for the presence of Salmonella by Dr. Lucas de Assunção, professor of bacteriology of the Faculdade de Saude Publica e Higiene of São Paulo. Of the 153 samples analyzed, 15 per cent were found to be positive. Dr. Lucas Assunção examined meat and entrails of pork, beef, kid, mutton and chicken. The pork products gave the highest number of positive tests, the most contaminated organ being the liver. The incidence was found to be less in beef (10.6 per cent) than in pork (19 per cent). Of 7 samples of kid meat analyzed 1 was positive (14.2 per cent) and also 1 out of 10 chicken samples Of 55 cultures of salmonella isolated, 25 were identified Of the nonidentified group some were not examined. Salmonella anatis, Salmonella give, Salmonella typhimurium, Salmonella cholerae suis (var. Kunzendorf), Salmonella newington, Salmonella london, Salmonella derby and Salmonella paratyphi B were the types of Salmonella isolated and classified according the Kauffmann-White scheme

Treatment of Intestinal Amebiasis

Dr. Felicio Cintra do Prado, professor at the Escola Paulista de Medicina, in a symposium describes a comparatively simple general method for the treatment of amebiasis Treatment is effected in four months, during which the specific arsenical and iodoquinoleinic medicaments are alternated, always orally, in weekly consecutive series; emetine is administered only to stop the diarrhea and for the extraintestinal localization of Endameba histolytica The specific medication must be complemented by hygienic and dietetic measures and by auxiliary medication intended to attack intestinal infections frequently associated with amebiasis. Symptomatic, antispasmodic and sedative treatments are useful in many cases.

Professor Cintra do Prado based his work on a few hundred observations made in his private clinic. He selected 140 cases and followed them up closely for over a year. The therapeutic results in the 140 cases were as follows: complete clinical cure in 98 cases (70 per cent), the amebas having disappeared from the feces; incomplete cure in 24 cases (17.1 per cent), as notwithstanding negative parasitologic tests of the feces the patients remained subject to sporadic intestinal disturbances; poor results in 18 cases (12 per cent) (16 cases of clinical amelioration and negative tests but persistence of colitis with varied general repercussions; 2 cases of relapse within one year, probably caused by reinfection).

PERU

(From Our Regular Correspondent)

May 27, 1947.

Pan American Tuberculosis Congress

The seventh Pan American Tuberculosis Congress was held in Lima, Peru, March 17-22. Brazilian official speakers were Dr. Manoel de Abreu on "Examination of Workers," Dr. Eduardo Etzel on "Tuberculous Tracheobronchitis" and Dr Cezar de Araujo on "Social and Economic Protection of Tuberculous Patients." Drs. A. Nogueira Martins and B. Pedral Sampaio, Brazilian co-speakers and representatives of the government, spoke on "Results of Examinations of Workers in São Paulo."

The congress resolved, on the first topic, (1) to broaden the examination of workers by extending periodic tuberculin tests and roentgenographic tests (Manoel de Abreu's method) eventually to all groups; (2) to establish the practice of carrying on examinations of workers in state institutions, the Social Insurance and the Beneficence, and by means of portable x-ray units to give such benefits to people living in suburban and rural communities.

On the second topic, the congress resolved that (1) tuberculous tracheobronchitis includes bronchoscopic lesions of the trachea and large bronchi only: however, it is necessary to consider the lesions of the small bronchi, which cannot be visualized by bronchoscopy as a part of the disease; (2) routine bronchoscopy is recommended in all cases with suggestive clinical and x-ray symptoms; systematic bronchoscopy is reserved to departments lacking in a specialized section for peroral endoscopy; (3) bronchial lesions in general do not contraindicate the treatment of pulmonary tuberculosis by the method of either collapse or resection; (4) the creation of specialized departments for this examination in all centers for the care of tuberculous patients is advised

On the third topic the congress recommended the establishing of measures for the social and economic protection of tuberculous patients which permit them to have adequate treatment and requested the governments of all Latin American countries to revise the social regulations on work, communicable diseases, industrial hygiene and social insurance with the aim of improving the protection of tuberculous patients and the public.

Correspondence

FATAL ALLERGIC REACTION TO INFLUENZA VACCINE

To the Editor:—In Clinical Notes in The Journal, April 12, appears a report by Dr. Theodore J. Curphey of a case purported to represent a fatal allergic reaction due to influenza vaccine. The implication is made that egg antigen contained in the vaccine was the responsible exciting factor. In a letter to the Editor in The Journal of May 31 Dr. David Louis Engelsher comments on this case and states that in his opinion the death was due to sensitivity to the bacteria of the vaccine and not to the contained egg.

Aside from the fact that the 3½ year old patient became violently ill four hours after receiving a subcutaneous injection of 0.5 cc. of stock influenza type A and B vaccine and died eleven hours after the injection, there is little in the entire report to support the diagnosis of allergy. There was no known family history of allergy. The past personal history of allergy on which Dr. Engelsher rests his specific diagnosis is highly questionable, to say the least. The assumption of a positive past personal history of allergy is based on the following remark in the report: "It was stated, however, that the child had had hives for one day during the first year of life, which were thought to follow medication with acetylsalicylic acid."

No passive transfer study of the postmortem blood for the identification of egg or other reagins is mentioned, though a failure to have found them would not have been conclusive evidence against the existence of sensitivity to egg.

The relatively long interval of four hours between the injection and the first appearance of severe symptoms, the absence of characteristic allergic manifestations, the clinical course and the autopsy findings are not at all suggestive of an intense allergic phenomenon.

In their review of 26 cases, including 7 of their own, of sudden death following injection of foreign protein, Vance and Strassmann in 1942 stressed the fact that most of the cases presented clinical signs or pathologic lesions in the lungs indicating death by asphyxia. The onset was sudden, respiratory difficulty starting immediately or within ten to thirty minutes after the injection, death occurring within a few minutes or after a few hours. In 21 of the 26 cases death occurred within one hour following the injection, in most instances in a few minutes. At autopsy the lungs were found inflated with air. Microscopically, among other changes, eosinophilic infiltration into the bronchial nodes or into the submucosa of the bronchi was present in every case in which a microscopic examination was made; in 2 out of 6 cases, in addition, eosinophils were found in the submucosa of the gastrointestinal tract, in the spleen and in 1 instance also in the liver.

In the one set of identical twin infants who died after a second injection of diphtheria toxoid and pertussis antigen, alum precipitated, reported by Werne and Garrow in June 1946 there was neither clinical nor pathologic evidence of bronchial obstruction of a degree sufficient to cause death. However, there were a positive family history of allergy, extreme narrowing of some bronchial lumens, numerous eosinophils in the lymphatic tissues and slight eosinophilic infiltration into both bronchial and pulmonary arterial walls, the arterial walls of the thymus showed an eosinophilia, the sinusoids of the liver contained a moderate number of eosinophils and there was some eosinophilic infiltration into the vascular and perivascular structures of the brain. This eosinophilic response was present along with other evidence of vascular injury.

Dr. Curphey's case exhibited no characteristic allergic clinical symptoms or signs; pathologically, the presence of generalized visceral hemorrhage and the presence of "only occasional eosinophils" in the sections of the lungs and of moderate eosinophilic infiltration of a lymph node do not by themselves constitute sufficient ground on which to make a diagnosis of allergy.

It is my belief that the case reported is not one involving the reaction of hypersensitivity. There is much in the report to suggest a hyperacute, fulminating type of infection, possibly in the nature of the Waterhouse-Friderichsen syndrome, notwithstanding the absence of hemorrhage into the bilaterally atrophic adrenals, as the cause of death.

S. Senior Sack, M.D., Flushing, N. Y.

Examinations of the National Board of Medical Examiners and the Examining Boards in Specialties were published in The Journal, July 5, page 915.

BOARDS OF MEDICAL EXAMINERS

California: *Written.* Los Angeles, Aug. 25-28. *Oral.* San Francisco, July 19-20. Sec., Dr. Frederick N. Scatena, 1020 N. St., Sacramento 14.

Delware: *Endorsement.* Dover, July 15. Sec., Medical Council of Delaware, Dr. J. S. McDaniel, 229 S. State St., Dover.

Georgia: Atlanta, Oct. 14-16. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta 3.

Idaho: Boise, July 14-16. Sec., Bureau of Occupational Licenses, Dr. S. M. Poindexter, Eastman Bldg., Boise.

Kentucky: *Examination.* Louisville, Sept. 22-24. Sec., State Board of Health, Dr. P. E. Blackerby, 620 S. Third St., Louisville 2.

Montana: Helena, Oct. 6-8. Sec., Dr. Otto G. Klein, 302 N. Main St., Helena.

New Hampshire: *Examination.* Concord, Sept. 11-12. Sec., Board of Registration in Medicine, Dr. John S. Wheeler, 107 State House, Concord.

North Carolina: *Endorsement.* Morehead City, July 31. Sec., Dr. Ivan Proctor, 226 Hillsboro St., Raleigh.

South Dakota:* Pierre, July 15-16. Sec., Medical Licensure, State Board of Health, Dr. Gilbert Cottam, Capitol Bldg., Pierre.

Washington:* Seattle, July 14-16. Sec., Miss Virginia Wotherspoon, Department of Licenses, Olympia.

---

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: Juneau, First week in August. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

Arizona: Sept. 16. Sec., Mr. Francis A. Roy, Science Hall, University of Arizona, Tucson.

Colorado: *Examination.* Denver, Sept. 17-18. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

District of Columbia: *Examination.* Washington, Oct. 20-21. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6012 E. Municipal Bldg., Washington.

Florida: *Examination.* Gainesville, Nov. 1. Final date for filing application is Oct. 16. Sec., Dr. W. M. Emmell, University of Florida, Gainesville.

Michigan: *Examination.* Ann Arbor and Detroit, Oct. 10-11. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing.

Nebraska: *Examination.* Omaha, Oct. 7-8. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, State Department of Health, Room 1009, State Capitol Bldg., Lincoln 9.

New Mexico: *Examination.* Santa Fe, Aug. 3. Sec., Miss Marion M. Rhea, % State Land Office, Santa Fe.

Oklahoma: The date for the next examination has not been set as yet but will be sometime in the spring of 1948. Sec., Dr. Frank Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon: *Examination.* Portland, Sept. 6. Final date for filing application is Aug. 20. Sec., Board of Higher Education, Basic Science Examining Committee, Mr. C. D. Byrne, University of Oregon, Eugene.

Rhode Island: *Examination.* Aug. 13. Chief, Division of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

Wisconsin: *Examination.* Madison, Sept. 27. Final date for filing application is Sept. 20. Sec., Mr. William H. Barber, Watson and Scott Streets, Ripon.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Charitable Status of Hospital to Foster the Practice of Osteopathy.—The plaintiff hospital filed a proceeding against the Unemployment Compensation Commission of Missouri to review a decision of the defendant that services performed in the employ of the hospital are not excluded from the statutory definition of the term 'employment' as used in the unemployment compensation law From a judgment affirming the commission's finding, the hospital appealed to the Supreme *Court of Missouri*

The Unemployment Compensation Law provides that the term 'employment' shall not include '(F) service performed in the employ of a corporation community chest fund, or foundation organized •and operated exclusively for religious charitable, scientific, literary, or educational purposes or for the prevention of cruelty to children or animals, no part of the net earnings of which inures to the benefit of any private share holder or individual, ' The Northeast Hospital was first incorporated in January 1936 under the laws of Missouri governing manufacturing and business corporations On Dec 27, 1940 the present corporation was formed by a pro forma decree of the Circuit Court under the name of Northeast Hospital It acquired the business and assets of the original Northeast Hospital, a corporation, which was dissolved and continued the operation of the hospital On Jan 31, 1944 the name of the corporation was changed to Northeast Osteopathic Hospital, the name by which it is now known by decree of the same court

The hospital contends that it is a corporation "organized and operated exclusively for *charitable* purposes" The commission held as a matter of law and decided (and the decision was affirmed by the *reviewing court) that services* performed by all persons in the employ of the hospital "are in 'employment' within the meaning of the term 'employment' as it is defined in the unemployment compensation law, and that no part of such services are excluded from the definition of 'employment' subject to the law by the provisions" of section 9423 (1) (6) (f) The Supreme Court said that the hospital, organized under the laws governing manufacturing and business corporations, had no shares of stock (hence no share holders) Under the facts the hospital is operating on a nonprofit basis in the sense that no part of net earnings inures to the benefit of a private individual

Among the purposes of the organization, as stated in the Articles of Incorporation are the following Fourth This association is formed for the purpose of owning operating and maintaining the Northeast Hospital Kansas City, Misssouri, and such other hospitals or institutions as it may in the future acquire, to foster and encourage the study and practice of osteopathy, to foster and encourage scientific research, to buy, sell, mortgage, encumber, lease and deal in land and buildings in Kansas City and elsewhere for the purpose of fostering and encouraging the study and practice of osteopathy, to buy, sell, mortgage, and encumber, lease, and deal in equipment and other personal property which may be necessary to provide facilities for the study and practice of osteopathy, to employ interns, nurses, and others to carry on the work of the Northeast Hospital and such other hospitals or institutions as this association may acquire, to do each and every act which may be necessary to carry out the purposes for which this association is formed"

It is contended by the hospital that sole resort must be had to its charter for determination of the claimed exemption The cases cited in support of this contention, said the Supreme Court, are in harmony with the general rule that the purpose of an organization must be determined from the purpose declared in the instrument creating it In other words, the Supreme Court continued, the hospital must demonstrate itself to be both organized and operated exclusively for charitable purposes in order to be excluded by the provisions of the unemployment compensation law Was hospital organized and is it operated exclusively for charitable purposes? Hospital asserts it was and is Commission, a tax collecting agency in a sense, has the right in this case to challenge the claim of immunity from taxation which the hospital seeks to invoke Briefly, said the court, it has been stated that the test in determining whether a hospital is charitable or otherwise is whether or not it is maintained for a gain, profit, or advantage The plaintiff hospital's pro forma decree of incorporation did not recite or recognize hospital s corporate purpose as charitable, while the hospital's charter includes the purpose of operating a hospital, or hospitals, the articles are not otherwise expressive of a charitable purpose Some purposes, additional to that of maintaining a hospital, as stated in the articles of agreement are "to foster *and encourage* the study and practice of osteopathy" and to "buy, sell mortgage, encumber, lease, and deal in" realty and personalty "which may become necessary to provide facilities for the study and practice of osteopathy", *and the fact that the hospital* 'provides facilities for the *practice of osteopathy*" was *also* found as a fact by commission's special representative, whose findings were adopted by the *commission* Perhaps *all* hospitals in some degree further and provide facilities for the practice of the *practitioners of some school or* schools of the science of healing, said the court, but would a corporation organized for the *purposes of fostering and* encouraging and providing facilities for *practice of some school* or schools of the science of healing be a corporation organized exclusively for charitable purposes—*even though* the corporation also had the purpose of maintaining a hospital, and even though no part of the net earnings of a corporation inured to the benefit of a share holder or a private individual? This brings us, said the court, to an examination of the meaning of the word "exclusively" Manifestly the *exemption* in the unemployment compensation law is in recognition of the great benefit the public derives from institutions *exclusively* charitable A substantial noncharitable purpose of the hospital's organization should be fatal Otherwise, by a noncharitable purpose of organization, a corporation, although it were also organized for a charitable purpose, would or could in the exercise of its noncharitable power, exploit its noncharitable purpose and destroy or materially shade the fulness of its committed service in the public welfare and all the while defeat the purpose of the law under the guise of the charitable purpose The purposes of fostering and encouraging and providing facilities for the practice *of osteopathy*, said the Supreme Court, are quite clearly professional and not charitable in nature It should not be held that the purpose of fostering, encouraging and providing facilities for the practice of a profession are charitable within the meaning of the unemployment compensation law, and such purposes if they are seen to be substantial, should prevent a hospital's exclusion from the purview of the unemployment compensation law In the hospital's statement of corporate purposes there is an absence of a clear expression of a plotted, primary, dominant objective to foster and encourage the relief of, and provide facilities for the hospitalization of, those who are diseased or injured or who suffer constraint in body or mind—this in our opinion lends emphasis to and conclusively demonstrates the substantiality of the expressed non charitable purposes The whole record justifies the conclusions that the hospital was organized and the hospital operated by osteopathic physicians for the purposes of fostering and encouraging and providing facilities for the practice of osteopathy and that the maintenance of the hospital is but importantly incidental to such purposes Accordingly the judgment affirming the decision of the Unemployment Compensation Commission was affirmed by the Supreme Court—*Northeast Osteopathic Hospital v Keitel, 197 S W (2d) 970 (Mo, 1946)*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). *Periodicals published by the American Medical Association* are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Pathology of Mitral Valve in Older Age Groups. J. Rosenthal and I. Feigin.—p. 346.

Pulmonary (Venous) Air Embolism.—Durant and his co-workers stress that pulmonary (venous) air embolism must be differentiated from the arterial form of air embolism. In the pulmonary form, air enters one of the systemic veins and is carried to the right side of the heart and pulmonary circulation and depends for its effects on mechanical obstruction of the outflow tract of the right ventricle. In arterial embolism the air gains entrance to the pulmonary venous channels and is propelled from the left ventricle to those systemic arteries which supply the superiorly located portions of the body. Since a small amount of air can effectively block a medium size artery, serious consequences may result when a few cubic centimeters of air enter the pulmonary vein and are carried into either the coronary or cerebral circulation or both. In the pulmonary, or venous, form the presence of air in the right ventricle produces a loud, churning sound, often readily heard without stethoscopic aid, which is known as the "millwheel" murmur. This murmur appears almost immediately after air has entered the venous circulation. As a result of the obstruction of the right ventricular outflow tract from the air trap which forms within it, the venous pressure rises to a considerable degree and cyanosis becomes apparent. There also appear manifestations of forward circulatory failure, namely a falling blood pressure, a rapid thready pulse, and syncope due to cerebral ischemia. The authors investigated the mechanism of death in pulmonary air embolism and means of preventing this occurrence. Death is due to circulatory obstruction resulting from an air trap in the right ventricular outflow tract. Displacement of the air trap by turning the body into the left lateral position may be life saving even after the right ventricular contractions have become feeble and death seems imminent.

Preliminary Report on Field Experiments to Demonstrate Effectiveness of Various Methods of Malaria Control. J. E. Elmendorf Jr.—p. 135.
Radical Cure of Avian Malaria (Plasmodium Cathemerium) with SN 8557, A Naphthoquinone Derivative. W. Gingrich, Eugenia W. Schoch, Marjorie Schwab and Catherine C. Shepherd.—p. 147.

Pacific Vivax Malaria in American Negroes.—A group of American white and Negro troops stationed in a highly malarious area of the Pacific were studied to determine their comparative response to Pacific vivax malaria. There was no difference in the incidence of primary or recurrent malaria between the two races. Clinical and epidemiologic observations likewise indicated a similar behavior in regard to this disease. *Natives of this area manifested tolerance to the vivax malaria* of their neighborhood. This indicates that the American Negro lacks racial tolerance to the strains of vivax malaria encountered in the Pacific.

Use of Crotalin in Prevention of Anaphylactic Shock in Guinea Pigs. D. E. Frank.—p. 156.

Benadryl in Allergic Diseases in Children.—Logan reports the results of the use of benadryl in the treatment of asthma, hay fever, vasomotor rhinitis and urticaria in 71 children. Six of 7 children treated for a single attack of asthma were considered benefited to some degree, and 16 of 17 treated for multiple attacks also obtained some benefit. Eleven of 13 children treated for hay fever obtained some benefit, as did 16 of 18 children treated for vasomotor rhinitis. Fifteen of the 16 children treated for urticaria obtained some benefit. Seventeen of the 71 children had as undesirable reactions, drowsiness, vomiting, nausea, headache, crabbiness, tachycardia or hematuria.

Administration of the drug to 6 of the 17 children was stopped because of the reaction. The doses ranged from 10 to 450 mg per day. This study indicates that benadryl is a valuable addition to drugs used in the symptomatic treatment of allergic diseases in children.

Acid Débridement of Burns.—Sulzberger's group compared the pyruvic acid-starch paste method with other methods on symmetrically situated small standard third degree thermal and chemical burns on the flexor aspects of the forearm of male subjects. They found that treatment with pyruvic acid-starch paste and, subsequent to slough removal, with sodium sulfadiazine cream produced more rapid healing than (*a*) leaving the lesions untreated or (*b*) treatment under pressure bandage with 5 per cent sodium sulfadiazine cream or (*c*) with 5 per cent sulfadiazine cream or (*d*) with ⅕ per cent silver nitrate in petrolatum. The effects of acid débridement are not specific for pyruvic acid but appear to be dependent on the maintenance of the correct supply of hydrogen ions over a sufficient period. Among the other acids tested, 0.1 molar phosphoric acid, which has a p_H of 2.0 and which is a weakly dissociated acid, proved to be the best.

Hodgkin's Sarcoma of Uterus. H. N. Naumann —p 324.

Toxicity of Methyl Chloride.—Dunn and Smith review observations on seven species of animals which were exposed to concentrations of methyl chloride ranging from 4,000 to 500 parts per million for six hours a day six days a week until death. The eighth species studied was exposed to 11,000 parts per million for two hours a day on two consecutive days. On the basis of this study on several hundred animals, the majority mice, rats and guinea pigs, with fewer dogs, rabbits, cats, monkeys and goats, the only morphologic changes that appear to be a direct result of inhalation of methyl chloride are variable degrees of necrosis of the convoluted tubules of the kidneys in mice and rats, renal changes associated with hemoglobinuria in mice and occasional dogs, and a fairly constant but low to moderate amount of fatty metamorphosis of the liver and kidneys in the smaller species of animals studied. Clinically, pulmonary edema was noted frequently and appeared to be a direct result of the irritation due to inhalation of methyl chloride. Although focal myocardial changes and pneumonia were occasionally noted, they were often closely associated and did not appear to result directly from the inhalation of methyl chloride.

Id IX Chronic Arthritis. J. G Kuhns —p 349.

Ruptured Intervertebral Disk in the Cervical Region.—Kristoff and Odom report 20 cases of ruptured intervertebral disk of the cervical region. Of the 20 cases 16 were those of pure root compression and only 4 were those of cord compression. The high percentage of root compressions in this series, as compared with those in the older reports of ruptured cervical disk, may be due to their earlier recognition. The pathogenesis may be divided into three states: (1) root compression, (2) unilateral cord compression with masked root compression and (3) bilateral cord compression with masked unilateral or bilateral root compression. A history of an initial and of repeated trauma was obtained in the majority of the cases. The diagnosis of a ruptured cervical disk is primarily clinical, and the history and subjective complaints are of maximal importance for arriving at an early recognition of the condition. Reproduction of the pain and paresthesias will be possible almost without exception as long as the syndrome is in the stage of root compression. After cord compression has occurred, myelography is the method of choice for arriving at a diagnosis of the level of the lesion. In the cases of lateral protrusions with root compression the operative results have been good. In the cases of cord compression recovery has not been always complete.

Streptomycin and Parachlorophenol in Surgical Infections.—In studies on streptomycin reported by Brooke the effect of streptomycin alone and its effect when mixed with agents such as sulfanilamide, penicillin, urea, tyrothricin, chloroazodin and parachlorophenol has been investigated. A mixture of streptomycin 500 micrograms per cubic centimeter and parachlorophenol 0.2 per cent was found adequate for the suppression of growth of all bacteria in vitro before treatment. In 10 cases infected burns, ulcers and wounds were treated locally with the streptomycin-parachlorophenol mixture as a solution or incorporated in various ointment bases, with generally good results. Streptomycin-resistant strains of the genus Pseudomonas developed in some instances after treatment, and the suggestion is made that perhaps local treatment with streptomycin should not be for long periods. The danger of development of resistant strains with prolonged use should not contraindicate use of streptomycin in selected cases. The injection of 200 micrograms of streptomycin per cubic centimeter into the periphery of some wounds seemed of benefit. It should be emphasized that these agents are only adjuvants and cannot replace surgical measures.

Hepatitis Following Transfusion.—Berk reports 43 instances of hepatitis out of a total of 72 which are believed to have followed transfusion of blood and/or plasma. Hepatitis developing after transfusion of blood, plasma or serum appears to be related to both homologous serum hepatitis and infectious (epidemic) hepatitis The evidence for this relationship is still incomplete. Posttransfusion hepatitis is associated with the greatest mortality of any of the groups of hepatitis thus far described There is reason to believe that the more serious nature of transfusion hepatitis is ascribable not to the disease itself but to the impaired protein and nutritional status of the patients who require transfusions

Total Pulmonary Decortication—*Samson* and Burford demonstrate the rationale of early decortication in selected patients with sterile organizing hemothorax, infected hemothorax and posttraumatic or hemothoracic empyema. The early restitution of pulmonary function has become a primary concern The crippling effects of chronic fibrothorax are preventable. Proper timing is of great importance in decortication. If attempted within ten to fourteen days in uninfected patients the peel is thin and friable. When performed too late the fibrous union between peel and pleura prevents a clean separation and the lung frequently is torn. From a technical standpoint the peel is most easily removed in from three to five weeks in uninfected patients and usually somewhat earlier when infection develops rapidly. The authors performed decortication on 125 patients and there have been no operative deaths.

Pulmonary Cysts.—Moersch and Clagett present 2 cases that would indicate that carcinoma may develop within a pulmonary cyst. The treatment of pulmonary cysts is entirely surgical. The type of operative procedure depends on the location, attachment, pulmonary involvement and secondary complications present. The essential point is to remove the cyst in its entirety.

Hematologic Changes in Lead Poisoning.—Machle says that lead interferes with synthesis of protoporphyrin and alters the reticular substance but that there are no specific hematologic changes in lead absorption Two changes occur with sufficient frequency and of such an order of magnitude as to be useful diagnostic aids. These are punctate basophilia (or stippling) and reduction in hemoglobin Stippled cells are present in nonexposed, normal persons at times in numbers up to 7,000 per million In diseases other than lead poisoning (hepatic cirrhosis, pulmonary disease) and especially in the blood dyscrasias, stippled cell counts as high as 50,000 per million may occur without associated lead exposure Hazardous lead absorption usually but not always causes elevations in stippled cell counts Basophilic stippling becomes significant as regards lead absorption with employment of a uniform method for which normal ranges of values have been defined, when repeated frequently on groups and used as an index of trends in exposure and as supportive evidence in the diagnosis of lead intoxication Hypochromic anemia is even less specific than stippling, since it frequently results from environmental factors, undernutrition and disease. Moreover, the degree of reduction in hemoglobin is never great, and the mean levels for groups do not always relate well to the magnitudes of exposure

Exposure to Lead.—Kehoe summarizes the available information with regard to (1) the significance of the exposure of the public to lead, (2) certain aspects of industrial exposure to lead and (3) the problem of diagnosis The importance of factors such as particulate lead in the atmosphere and the lead content of food and beverages, particularly in the drinking water, are considered. The degree of risk associated with occupational exposure to lead is the joint function of the severity of such exposure and its duration The problem is to determine the limits of safe occupational exposure to lead by providing criteria which can be applied pragmatically and by determining the physiologic facts concerning the relative importance of duration versus intensity of exposure under a variety of conditions. There is now available specific and fairly precise knowledge of the physiologic background by which one can estimate the significance of lead exposure and absorption Persons do not get lead poisoning without having absorbed abnormal quantities of lead

Ligation of the Inferior Vena Cava in Thrombosis of Deep Veins of Lower Extremities.—Veal and his associates have performed ligation of the inferior vena cava in 30 cases of ascending thrombosis of the deep veins of the lower extremities. Of these 25 were due to phlebothrombosis, 3 to femoroiliac thrombophlebitis and 2 to thrombophlebitis in varicose veins There were 28 instances of pulmonary embolism before ligation of the inferior vena cava There were none following ligation There were 3 deaths 2 in cardiac patients and 1 in pneumonia. There has been adequate development of collateral venous circulation in all those who survived Women develop better venous collaterals than men.

Anticoagulants in Venous Thrombosis.—Murray uses the anticoagulants heparin and dicumarol. In his 400 postoperative cases in which an anticoagulant was administered, peripheral thrombosis did not occur and there were no cases of pulmonary embolism. In 371 cases of venous thrombosis in which treatment with anticoagulants was carried out with the objective of (*a*) preventing pulmonary embolism and (*b*) as treatment for the progressive thrombosis in the venous tree the results were satisfactory in that pulmonary embolism did not occur. The late effects of the thrombosis were less severe than in a control group The author used anticoagulants also in 149 instances of survival from an embolism Fifty-two of these were in a state of alarming shock. Striking improvement takes place in a few hours, once the effect on clotting time has been obtained. The pulmonary distress with dyspnea and pain and the embarrassment of heart action are diminished progressively in a short time, so that within a few hours there is a measurable change and within twenty-four to thirty-six hours the alarming symptoms have largely disappeared. It may take several more days before there is complete relief of all symptoms.

Androgen in Breast Cancer.—Adair has used testosterone propionate in approximately 200 cases of cancer of the female breast. He gives an intramuscular injection of 100 mg. three times a week, making a total dosage of 2,400 to 3,000 mg. Improvement is not to be anticipated when the cancer involves the soft tissue such as liver, lungs, brain and local skin recurrence, but striking improvement is obtained in most of the cases in which there is bone metastasis. It is probable that under the influence of testosterone the billions of cancer cells are "snowed under" by the copious deposit of calcium precipitates, especially in areas of bone destruction—a locking-in process where cell reproduction is difficult. In cases of widespread bony metastasis the use of testosterone propionate seems more efficacious and longer lasting than x-ray therapy. Although to date most work has been done on advanced breast cancer, recently work has been started on the early operable cases of breast cancer. Radical mastectomy is supplemented by large doses of testosterone implanted into the latissimus dorsi muscle or into the subcutaneous tissues near the wound at the time of the operation This combination has been used in 135 such cases to date. Two months after the operation further doses of testosterone will be implanted. The patient receiving testosterone therapy develops unpleasant masculinizing sequelae as evidenced by a deeper husky voice, hair on the face, pimples on the face and body—and an enlarged clitoris, but there is also usually, at least temporarily, a gain in weight, a feeling of well being, a loss of bone pain and a repair of the bone destruction. Testosterone may be employed on female patients with breast cancer at any age, while the estrogen therapy must be confined to patients of 60 years and older. Testosterone is not a cure for breast cancer; however, its effects are profound and gratifying

Chemical Factors in Pernicious Anemia.—According to King the knowledge of the chemical factors involved in pernicious anemia is extremely sketchy. Progress is blocked by the absence of an assay method other than that of human clinical trial—slow, difficult to perform, severely limited by the clinical material available and giving results of barely more than qualitative significance. The solution of the chemical problem waits *on the biologic. Idiopathic failure of the stomach to produce* an "intrinsic factor" which normally interacts with a dietary "intrinsic factor" prevents formation of the "liver factor," a *hormone which is stored in the liver and is essential for the* production of normal erythrocytes. Similar conditions may result from other causes, preventing normal supply of this hormone to the erythropoietic bone marrow tissue. The condition may be treated by oral or parenteral administration of concentrates of the hormone prepared from liver or by oral administration of stomach preparations which replace the deficient "intrinsic factor." The intrinsic (gastric) factor is a typically thermolabile protein, possibly a proteolytic enzyme. The nature of the intrinsic (dietary) factor is unknown. The liver factor is relatively thermostable; the available evidence suggests a polypeptide structure.

Paraganglion of Ductus Arteriosus.—Barnard says that a gland similar in structure to that of the carotid body was found when examining serial sections of the human ductus arteriosus. This gland appears to be additional to the aortic bodies and *similar glands so far described. Its position is constant* between the ductus arteriosus and the pulmonary artery. It is always in close association with nerves, some of which appear to be large *branches of the vagus.* It also has in its neighborhood nerve ganglion cells. It is itself very vascular. The functions of the gland are not known. From its structure it would appear that these would be similar to those of the carotid body, and it would be tempting to speculate as to its possible association with the closure of the ductus arteriosus. Although there are no recorded cases of tumors arising from this type of tissue in this situation, it is highly probable that it may at some time give rise to tumors in the mediastinum.

Changes in Kidneys in Carbon Tetrachloride Poisoning.—According to Woods, profound and sometimes fatal involvement of the kidneys in carbon tetrachloride poisoning has been recognized for some time. Three young men serving in the Navy became affected after dry-cleaning their clothes in a confined space with Pyrene obtained from fire extinguishers. It seemed clear at necropsy that the renal and not the liver damage was *responsible for death. In the liver, necrosis is* confined to the centers of the lobules; the remainder of the parenchyma *appears normal and there is evidence of early* regeneration about the *central foci. In the kidneys, however,* there is microscopic evidence of severe disturbance. The microscopic picture is indistinguishable from that found in the crush syndrome: the severe degeneration, with loss of cells and evidence of early regeneration in the second convoluted tubules and ascending limbs of Henle, the abundant casts seemingly derived from fragmented red corpuscles, together with the characteristic orange-brown or café-au-lait pigmented casts, are features common to the two conditions. It is suggested that the tubulovenous communications present may be largely responsible for the clinical and histologic features of this type of renal disease.

**Effect of Water on Gastric Motility: Test for Duodenal Ulcer.* A. W. Kay.—p. 448.

Calciferol in Tuberculosis.—Feeny reports observations on 150 patients with lupus vulgaris who were treated daily with 100,000 or 150,000 units of calciferol (vitamin D_2). The patients were under observation for four to twelve months. Local treatment was also given in 87 of the cases and general light baths in 14 cases. The success attained would have taken twice or three times as long before the introduction of calciferol therapy, but almost all patients were now independent of general light treatment. The treatment *appears to be increasingly efficacious* for the first nine months. The proportion of resistant cases was virtually the same as it had been before calciferol was used. The response of patients who had at any time been subjected to x-ray, radium or grenz ray treatment was the same as that in patients not so treated. Calciferol had no effect on lupus carcinoma. The incidence of intolerance was 23 per cent. When calciferol is given by mouth an alcoholic vehicle should be used. The addition of vitamin B was without effect on tolerance. The addition of calcium was without additional clinical benefit. In the second part of this report Sandiland and Franklin review their experiences with 21 tuberculous patients who were treated from twenty to fifty days with 25,000 to 100,000 units of calciferol and 3 mg. of vitamin B daily. *No clinical improvement* in the lung condition was noted in any patient. The 2 who had lupus in addition to pulmonary tuberculosis both showed immediate *improvement in the skin condition.*

Sand Fly Fever.—Fleming and his associates review observations on 664 cases of sand fly fever treated in two military hospitals in Italy. Other biting flies besides Phlebotomus papatasii may be vectors. The possibility of protracted infectivity should be examined. Evidence is adduced that persons who develop local skin reactions to the bites may have protection against the infection. The blood findings did not prove to be of much help in differentiating sand fly fever from other virus infections. The virus of sand fly fever has a special predilection for the meninges and should be considered in the differential diagnosis of meningitis in areas where the sand fly is prevalent. The fever is usually short and without sequelae.

Effect of Water on Gastric Motility in Duodenal Ulcer.—Kay points out that Carlson observed in 1916 that the ingestion of cold water inhibited gastric contractions. In 1943 Anderson confirmed this inhibition in normal subjects but found that in patients with peptic ulceration the cold water even stimulates gastric contractions. This abnormal response he called the "water reversal phenomenon." Kay reports the results of an investigation on the effect of water on gastric motor function. Ingestion of cold water inhibits gastric motility in normal subjects for about five minutes; hot water has a similar but briefer effect. In the presence of active duodenal ulcer gastric activity is either unaltered or even stimulated by the ingestion of water. The water test is therefore of value in the diagnosis of duodenal ulcer. There is evidence that the receptor point for this gastric response to water is in the duodenum. This duodenal mechanism is damaged by active ulceration but functions normally when the lesion has healed. The water test can therefore be used to provide evidence of healing.

*Accidents of Intolerance of Penicillin. L. de Gennes, H. Bricaire, C. Laroche and J. Nelhil.—p. 161.
Catabolic Osteoporosis: Osteoporosis in Hyperthyroidism and in Cushing's Disease. A. Lichtwitz.—p. 162.
*Cholinesterase and Arterial Tension. L. Libbrecht.—p. 163.

Penicillin Intolerance.—De Gennes and his co-workers report 4 instances of penicillin intolerance in persons who had received 300,000 to 500,000 units of penicillin daily for ten days with a total dose of 2,600,000 to 3,000,000 units. The intolerance manifests itself in one of three types: In the first group a mild, transitory rise of temperature during the first days of treatment does not require discontinuation of the drug, and late rise of temperature occurs on the ninth day of treatment, which may increase if administration of the drug is not discontinued. In a second group there is a rise of temperature and eczema, while in a third type there is fever and erythroderma resembling serum disease. The majority of cases of intolerance occurred when a new lot of penicillin of Canadian origin was employed, suggesting that the nature and the mode of preparation may play a part in the intolerance. It was also observed that acute leukemia may be responsible for sensitization. These untoward reactions do not contraindicate the use of penicillin in the presence of a severe infection.

Cholinesterase and Arterial Tension.—Libbrecht determined the cholinesterase rate by means of Ammon's manometric method in 74 patients with hypertension who presented an average of 71 cmm. of carbon dioxide, while 150 persons without hypertension had an average of 60 cmm. Forty-two of the 74 patients had essential hypertension and an average of 71 cmm. On the other hand, patients with renal hypertension presented an average cholinesterase rate of 63 cmm., i. e. about the same as the general average of those without hypertension. The blood cholinesterase appears to be proportional to arterial tension, since the latter is conditioned by the vegetative tonus. The normal cholinesterase rate in the serum of patients with renal hypertension is related to their humoral etiology, while the increase in the cholinesterase rate of the patient with essential hypertension is related to their sympathicotonic nervous origin. Essential hypertension was considerably reduced by administration of neostigmine with doses previously employed only for myasthenia gravis.

*Cancer of Thyroid. M. Tapia de la Maza.—p. 29.

Cancer of Thyroid.—Tapia de la Maza observed in the course of eight years in a clinic of Chile 34 patients with cancer of the thyroid among 613 patients with thyroid disease. The group included 30 women and 4 men between 23 and 70. The tumor developed in 9 patients without a previous goiter, in 2 patients with goiter and in 2 patients with toxic adenoma. The tumor developed from a thyroid adenoma in 21 patients. The clinical symptoms appeared late. The most frequent were those of local compression and rapid enlargement of the thyroid. Four patients presented no symptoms. The treatment consisted in an extensive thyroidectomy followed by radium therapy.

*Tuberculomas of Central Nervous System. A. Asenjo, F. R. Perino, E. Garcia S. and A. Gallo B.—p. 1.

Tuberculomas of Central Nervous System.—One hundred instances of tuberculoma of the central nervous system were observed during a period of five years in a group of 287 tumor patients in the Instituto de Neurocirugia de Santiago. The diagnosis was verified in 65 cases by microscopic study after removal of the tumor or by a necropsy. Tuberculoma was solitary in 38 cases and multiple in 27. Poor economic and nutritional conditions in early adult life, tuberculosis in the family and a previous anergy causing disease constituted the etiologic factors. Symptoms of increased intracranial tension were present in all. Therapy consisted in the general regimen for tuberculous patients and either decompression or enucleation of the tumor, which was performed only when the tuberculoma was well delimited and surrounded by apparently normal tissue. In the 35 cases in which a necropsy was performed, the tumor was surrounded by tuberculous tissue 1 or 2 cm. in thickness. The microglia was in a state of acute proliferation and macrophagia, whereas the astroglia remained normal.

Tularemia in Austria.—Puntigam discusses the epidemiology of two tularemia epidemics in the districts of Mistelbach and Gänserndorf of Lower Austria in 1936-1937 and 1945-1946. A considerable increase in the number of field mice was observed during dry summers. An epizootic developed in mice and caused their disappearance in November. From three to six weeks later first cases of the disease in man were reported. Only 1 out of 200 patients died in the first epidemic. There was no fatality among the 207 patients of the second epidemic. The observations suggest that mice act as a reservoir and main disseminators of Pasteurella tularensis. Additional investigations will probably demonstrate whether ectoparasites of these rodents or their excrements are responsible for the infection of the intermediary hosts, such as the field hares and wild rabbits. The question whether rats are to be considered as reservoir animals has not been answered. Infection in man is caused by contact with sick field hares or wild rabbits in the majority of cases. Other sources of infection such as domestic rabbits, chicken and roes (intermediary hosts) should be investigated. Transmission of Pasteurella tularensis to man by insects does not seem likely. Prevention of tularemia in animals and man can be accomplished only by a continuous radical campaign against mice and rats, even in times when there is no tularemia among field hares and wild rabbits.

per cent. It is pointed out however that, while the habits were recorded at the time of application, the higher mortality than usual may be due largely to a proportion of the applicants becoming immoderate drinkers at a later date. The death rate in this group was higher than the normal from cirrhosis of the liver, cerebral hemorrhage and pneumonia.

By comparison, whereas some members of the "moderate drinker" group were allowed policies at the normal rates of premium, another group, which consisted of those who drank to excess not oftener than three times a year but whose bouts lasted two or three days at a time, were considered as distinctly hazardous risks, with a relative mortality of 331 per cent.

SOUND DETECTION OVER HEART AND BLOOD VESSELS

To the Editor:—What is the intensity of the sound, in decibels, of (1) the radial pulse of a normal man, (2) that sound after it has been amplified by a conventional stethoscope and (3) the heart beat of a normal adult man at the apex?
Aaron Coblenz, M.D., New York.

Answer.—The decibel is defined as the power of the sound level which is just at the threshold of hearing. A 1 decibel variation is approximately the minimal change in the power level of sound that can be detected by the average human being.

1. It is apparent that the intensity of the sound of the radial pulse of a normal man is considerably below the threshold of hearing, and it probably is of the order of only a few per cent of 1 decibel in strength.

2. The conventional stethoscope does not amplify sound but merely acts to transmit the sound waves from the bell to the ear via rubber and metal tubing, thus reducing the normal loss in intensity due to distance, although certain distortions in the sound are introduced. Under ordinary conditions in the arterial tree, the sound induced by the phasic flow of blood is considerably less than 1 decibel. Whenever an artery is constricted, as with the application of the sphygmomanometer cuff, the turbulence of blood flow and the slapping of the arterial wall at the site of constriction create considerable noise and this is sufficient for utilization in the indirect measurement of the arterial pressure. Under these conditions as much as 35 decibels of power of sound level may be produced.

3. Several factors participate in the intensity of the sound heard at the apex: those involved in the psychology of hearing, in the adequacy of the ear for certain frequencies of sound, in the physics of sound transmission, and in the special properties of the thoracic tissues through which the sound is transmitted. There are many paths along which the heart sounds travel in the body before reaching the surface. A large percentage of the sound energy never reaches the surface because of viscosity, elasticity, density, spreading, reflection and refraction losses. The intensity of these sounds is maximum over the portion of the chest where the sound pursues a path of minimal attenuation. The greater the pressure with which the open stethoscopic chest piece is applied to the chest, the better is the response of the stethoscope, especially to higher frequency components. The diaphragm type of stethoscope reduces the intensity of the higher frequency components and may increase the intensity of certain low frequency components which are harmonics of the characteristics of the diaphragm. Finally, the human ear is a better detector of changes of frequency than of changes in intensity. It is apparent that the intensity of the sound at the apex may vary greatly with rather slight changes in conditions. The noise level at the apex as usually recorded via stethoscope is of the order of 20 to 35 decibels.

TESTS FOR PORPHYRINURIA

To the Editor:—Which is the more accurate and efficient test for the routine examination of urine for the presence of porphyrins: the B. E. S. test of Spies and Ellinger (described in Duncan "Diseases of Metabolism") or the test of C. J. Watson, using Ehrlich's reagent and a saturated solution of sodium acetate and concentrating the pigment in chloroform?
Clifford W. Atherton, M.D., Fairview, Ill.

Answer.—The B. E. S. test of Spies and Ellinger is not specific for porphyrin, since other urinary pigments will give a positive test, particularly urorosein. A positive test is thought to indicate malnutrition before the appearance of diagnostic evidence of a deficiency disease. However, the test is not in general use today.

The test for urinary porphobilinogen of Watson and Schwartz is a reliable test and is positive in cases of acute idiopathic porphyria. It is not positive in congenital idiopathic porphyria. The test is simple and can be carried out in any physician's office, but care must be taken to use exact proportions of the reagents. The technic is as follows:

1. The urine must be a freshly voided specimen.

2. Acidify with 10 per cent hydrochloric acid until a p_H between 3.5 and 5.0 is reached. (It should compare with p_H 4.5 of nitrazine paper but not give a blue color with congo red paper.)

3. Mix equal parts of urine and Ehrlich's reagent in a test tube.

4. If a red color is obtained, add an equal volume of a saturated aqueous solution of sodium acetate.

5. Add a few cubic centimeters of chloroform and mix thoroughly.

6. The red aldehyde compound of porphobilinogen remains in the aqueous fraction, while that of urobilinogen or indole is completely extracted by chloroform.

7. Ehrlich's Reagent: 0.7 Gm. of p-dimethylaminobenzaldehyde; 150 cc. of concentrated hydrochloric acid; 100 cc. of distilled water.

PENTOTHAL ANESTHESIA FOR CESAREAN SECTION

To the Editor:—Are there any contraindications to the use of sodium pentothal, with or without curare, for cesarean section? Will it interfere with the baby's respirations?
R. E. Speirs, M.D., Dodge City, Kan.

Answer.—Sodium pentothal in large doses produces results similar to older general anesthetic agents. Sufficient abolition of reflexes and relaxation of muscles usually required for abdominal operations is often accompanied by depression of breathing. Curare at present is considered a useful adjunct to anesthesia because it paralyzes skeletal muscles. The dose necessary to relax the muscles of the abdominal wall completely is just short of the dose which paralyzes the muscles of respiration. Hence both these drugs, when used to produce satisfactory conditions for cesarean section, must include the risk of decreasing the ventilation of the lungs or of stopping respiration altogether. If the anesthetist is clever and experienced enough to administer adequate and proper doses of a combination of pentothal and curare without decreasing unduly the mother's respiratory exchange, the method might be justifiable. However, few physicians would feel confident that they could thus produce sufficient anesthesia without risking, at least in an occasional case, secondary depletion of the oxygen supply and an accumulation of carbon dioxide in the child before birth. Both drugs can be expected to pass through the placenta to the fetal circulation. In sufficient dose, the initial breath of the newborn might be delayed or prevented. If these drugs are used, artificial respiration with oxygen should be instantly available and applied promptly when breathing becomes inadequate either in the mother before birth or in the newborn child. There are many safer and better methods of producing anesthesia for this operation.

MYASTHENIA GRAVIS AND PREGNANCY

To the Editor:—A primipara secundigravida aged 28 has myasthenia gravis. Please discuss (1) the antepartum management, (2) the management of delivery with particular reference to medications contraindicated and anesthesia and (3) the complications to be expected.
M.D., Massachusetts.

Answer.—1. Except for the addition of neostigmine therapy antepartum care for women with myasthenia gravis does not differ from the care given other women. Before the use of neostigmine pregnancy was frequently terminated, but this is not necessary if the patient can be controlled with neostigmine. Generally the effect of pregnancy on myasthenia is favorable. Most women experience definite remission in symptoms, and if relapses occur they are mild.

2. Management of delivery is the same as in other women. The same drugs and anesthetics may be used, but the fewer that are administered the better. For actual delivery, local anesthesia should be tried because it is the least dangerous of all anesthetics.

3. Complications need not be expected, because pregnancy, labor and nursing do not affect the course of the disease unfavorably under present conditions of treatment. There is an excellent article on this subject by H. R. Viets, R. S. Schwab and M. A. B. Brazier in The Journal, May 16, 1942, page 236.

DIAGNOSIS OF MYASTHENIA GRAVIS IN PATIENTS WITH. DYSPHAGIA

HENRY R. VIETS, M D
Boston

Dysphagia is one of the commonest symptoms of myasthenia gravis. Moreover, it may often be the presenting symptom, some difficulty in swallowing being the first sign of abnormal muscular fatigue. The defect in the swallowing reflex is due to weakness of the buccopharyngeal muscles, usually with relaxation of the constrictors. Both the feeble power of the reflex act, as shown by the slowness of movement, and the relaxation, with dilation of the pharyngeal tube, are easily demonstrated by roentgenoscopic examination. The tightening of these muscles and the increased rate of swallowing, after stimulation by an appropriate amount of neostigmine ("prostigmine") methylsulfate, was observed and recorded in cases of myasthenia gravis by Schwab and Viets[1] in 1941. They suggested that this method of examination might be used as a test for the disease, and the present communication is in effect a reinforcement of the observations of 1941 in the light of five more years of experience.

DYSPHAGIA AND DYSARTHRIA IN MYASTHENIA GRAVIS

In the last eleven years, 175 cases of myasthenia gravis have been studied at the Massachusetts General Hospital. An analysis of this entire group indicates that dysphagia and dysarthria occur at the onset as the first symptom in about 20 per cent of the patients. Thirty-five of the 175 patients had one or both of these symptoms (fig. 1). Dysphagia is commoner than dysarthria, although usually the two occur together. The dysarthria, indicated by nasal speech, seldom occurs alone and is to be considered as a minor symptom. The defect is in the soft palate, not in the vocal cords. Dysphagia, on the other hand, often may be present without any dysarthria.

In addition to being the first symptom in myasthenia gravis, dysphagia may occur in the course of the disease, at which time it is usually indicative of an exacerbation. Dysphagia is one of the more important symptoms, moreover, from the point of view of prognosis. When present the patient may lose weight rapidly and be subjected to choking or coughing spells. As a symptom, therefore, dysphagia is of more importance, except for dyspnea, than, for instance, ptosis and diplopia or general muscular weakness.

The first symptoms of myasthenia gravis occur at all ages, but the disease begins most frequently between the ages of 20 and 30 (fig. 2). Fifty-two of the 175 cases studied began during this decade. It is also relatively frequent between 60 and 70 years of age. From the point of view of the laryngologist, this later period becomes of considerable importance, for between ages 60 and 70 is the period when other forms of dysphagia, particularly those due to intrinsic degenerative diseases of the central nervous system and obstruction caused by tumor formation, are commonest. Bulbar palsy occurs at this age of life.

Myasthenia gravis, moreover, may occur in patients over 70, and I have had 10 such instances. In the younger age groups, 4 have occurred before the age of 10 and 26 between 10 and 20 years of age. There is a scattering of cases between 30 and 60 years, and no decade of life is free from examples of the onset of this disease, save possibly the ninth.

Of all the symptoms, ptosis and diplopia are the commonest, occurring in 43.4 per cent of the 175 patients who were examined. Next in frequency is general weakness due to involvement of the arms and legs. This was found in 34.2 per cent. Weakness of the muscles of the neck occurs in 2.3 per cent. Dysphagia and dysarthria account for the remaining 20.1 per cent (fig. 1).

The disease, formerly considered fatal in a large percentage of cases, is now considerably controlled by the use of neostigmine either given orally or by injection. In this series, 35 patients have died in the course of eleven years, a mortality of 20 per cent. Before the use of neostigmine the death rate, over a similar period, would have been about 75 per cent.

The progress of the disease offers great variability. The symptoms of some patients are fixed for long periods of time. On the other hand, there is not infrequently a tendency toward progress by remissions and relapses. Thirty-one per cent of the patients have shown some tendency toward remission, and 14 per cent of the patients have had complete remissions during the period of observation. Spontaneous remissions may occur, no matter how severe the symptoms of the patients may be during the height of their relapse.

The symptoms of myasthenia gravis are entirely due to weakness of the muscular action. Except for the act of swallowing, the muscles involved are those concerned with voluntary movements. The muscle dysfunction is due to fatigue, with normal action usually possible after a period of rest. There are indications that the abnormal fatigue is caused by a chemical disturbance in the acteylcholine-cholinesterase balance

at the myoneural junction or possibly in the muscle itself. Whatever the mechanism giving rise to the symptoms, it is now accepted that neostigmine has an unusual effect in overcoming the excessive fatigue of muscular motion. When the drug is taken, either by mouth or parenterally, the response is often prompt and may be complete. As the effect of neostigmine on other diseases is either slight or nil, the drug is useful as a diagnostic agent.

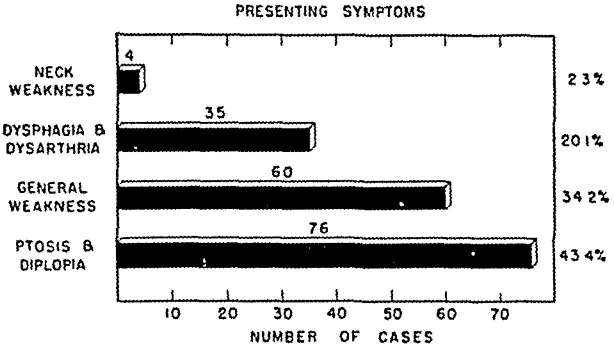

Fig. 1.—The first symptoms of myasthenia gravis in a group of 175 cases. Some defect in swallowing or speaking occurs in one fifth of the cases.

THE NEOSTIGMINE TEST

The neostigmine test may be carried out as an office procedure, but if the patient is seriously ill, the test is usually performed in the hospital. If the patient has not been taking neostigmine in any form and appears for diagnosis because of dysphagia, care should be taken in doing the test for two specific reasons. First, patients not suffering from myasthenia gravis may have a general reaction to the neostigmine and second, patients with bulbar palsy or other conditions giving rise to permanent muscular weakness may find it difficult to swallow the barium paste without choking.

For an adult, 1.5 mg. of neostigmine methylsulfate and 0.6 mg. of atropine sulfate are combined in a 1 cc. ampule, known as the diagnostic ampule. This special form of neostigmine should not be confused with the ordinary treatment ampule of neostigmine methylsulfate, 1 cc. of which contains 0.5 mg. of a 1:2,000 solution. Experience has shown that the amount of neostigmine in the diagnostic ampule is necessary in order to obtain a satisfactory test in an adult. The atropine is added to overcome the stimulation of the parasympathetic system. Ampules of atropine sulfate should be at hand to inject promptly provided the patient shows symptoms of severe parasympathetic stimulation, such as intestinal cramps, diarrhea, cold sweats or collapse. Most patients with myasthenia gravis are relatively free from reactions of this type. No patient is known to have died as the result of an injection of neostigmine as a diagnostic test, but the results may be disturbing to a roentgenologist who is not prepared to handle the situation. A violent reaction to neostigmine is almost certain evidence that myasthenia gravis is not the correct diagnosis.

If the barium paste is thick the patient may have considerable difficulty in swallowing it, particularly if suffering from permanent paralysis such as occurs in bulbar palsy. A thinner mixture should be used under these circumstances.

If the patient is taking neostigmine, the dosage of the drug should be omitted for at least twelve hours before the test is performed. In severe cases, only partial omission of the medicament may be possible. The examination is then made in the usual manner by observing the patient, ordinarily in the upright position, under the fluoroscope as the barium paste is swallowed. If the barium is retained in the pharynx a plate may be taken, thus recording the amount of retention. After the preliminary studies have been made, the patient is given a subcutaneous injection of the contents of the diagnostic ampule. In twenty to thirty minutes, reexamination is made following the same procedure.

ILLUSTRATIVE CASES

In most cases of myasthenia gravis, patients with dysphagia as the presenting symptom will respond to the neostigmine test completely. However, in mild cases the retention of barium in the pharynx before injection may not be pronounced, particularly if a thin solution of barium paste is used. After the injection the barium is completely removed, except for a minimum amount often left in the pyriform sinuses. This should be evacuated in the average patient after the second and third swallowing. In most cases there is no retention. No other disease except myasthenia gravis gives rise to such a complete return of normal function of the swallowing reflex after the appropriate amount of neostigmine is given and the patient is allowed to absorb the medicine over a period of twenty to thirty minutes. An example of this type of reaction which would be considered a positive neostigmine test, completely diagnostic of myasthenia gravis, is given in the following case history:

Case 1.—*History.*—H. R., a man aged 34, first noticed generalized muscular weakness with difficulty in chewing and swallowing in March, 1942. On examination two weeks after the onset there was ptosis of one eyelid, diplopia and inability to wrinkle the eyebrows or to close the eyes tightly. When his arms were extended in front of him they dropped in a few seconds. He fell when attempting to walk up some stairs. Because of the weakness of the muscles of the neck, he had difficulty in holding up his head. The act of swallowing was slow and labored, but there was no regurgitation of fluids through his nose. His jaw tended to hang half open, and his speech was slurred.

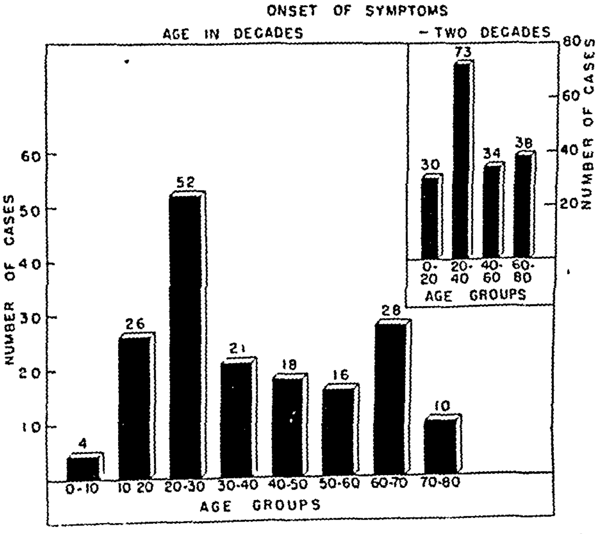

Fig. 2.—The age of onset in 175 cases of myasthenia gravis, by decades and double decades. Over 40 per cent of the group had their first symptoms between 20 and 40 years of age, but the disease began in all decades.

Roentgen Examination (March 19, 1942).—A swallow of barium was given and roentgen examination showed slight filling of the pyriform sinuses with little delay in the passage of the barium through the pharynx and upper esophagus (fig. 3 *A*). After injection of the neostigmine, the swallow was repeated and showed rapid passage of barium, with no filling of the pyriform sinus (fig 3 *B*). Examination of the swallow of barium before and after the injection of neostigmine showed definite changes in the muscular movements of deglutition.

Subsequent Clinical Course.—The patient responded well to neostigmine bromide taken at appropriate intervals by mouth. A thymectomy was performed April 21, 1943, and a benign thymoma was removed. The condition of the patient improved slightly immediately after operative intervention, but he subsequently had increasing symptoms and died of respiratory paralysis Oct. 15, 1944, about a year and a half after the operation. There was no thymic tissue present at autopsy.

In severer cases the response to the diagnostic ampule of neostigmine may not be so complete. Two of the ampules may be used, but usually one is sufficient. The roentgenologist should guard against making a mistaken report of "no improvement" when insufficient neostigmine has been employed. It is always better to repeat the test with an increased amount of neostigmine, if there is reasonable doubt in the mind of the examiner, and not accept an inconclusive result. If the barium paste is moderately thick no harm should come to the patient by repeating the test even at the same sitting.

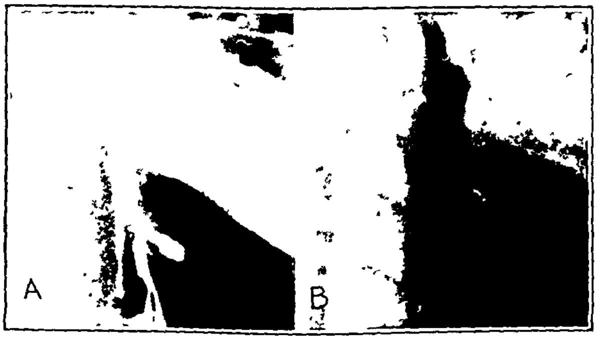

Fig. 3 (case 1).—*A*, appearance of the pharynx, showing slight retention of barium before injection of a diagnostic ampule of neostigmine methylsulfate. *B*, appearance of the pharynx after the injection of a diagnostic ampule.

Case 2.—*History.*—J. K., a woman aged 29, had experienced difficulty in swallowing and talking for about a month before being seen in December 1943 She had also noticed about the same time some intermittent weakness of the little fingers. On examination, she was unable to swallow any solid food and could swallow only a slight amount of liquid, without fatigue or regurgitation. Her voice was nasal in type to a sufficient degree that her speech was difficult to understand. Saliva tended to accumulate in her mouth. Ptosis of the left eyelid was present but no diplopia Some weakness of her legs was noticed in climbing stairs

Roentgen Examination (Dec. 30, 1943).—Before the injection of neostigmine roentgen examination showed decided retention of barium in the valleculae and pyriform sinuses (fig. 4 *A*). There was considerable difficulty in swallowing. The hypopharynx ballooned out considerably. After administration of neostigmine methylsulfate, the swallowing act was greatly improved and the tonus of the hypopharynx approached that of a normal person (fig. 4 *B*).

Subsequent Clinical Course.—The patient has been maintained reasonably well on a regimen of neostigmine bromide by mouth, supplemented with some injections of neostigmine methylsulfate, particularly before her meals. It was necessary for her to be hospitalized in 1945 in order to adjust her medical regimen. When she was properly maintained on an adequate dosage of neostigmine, the patient gained 10 pounds (4.5 Kg.) in a few weeks.

Occasionally, the improvement after injection may be insufficient to make a report of a positive test. Although the retention may be considerable, the increased rate of the swallowing reflex, as noted under the fluoroscope, is usually the most dependable observation. Much of the barium, moreover, may be removed on a second or third attempt to swallow, often an impossible act prior to the administration of neostigmine. A normal swallowing reflex, in spite of considerable retention of the barium, is illustrated by the following case:

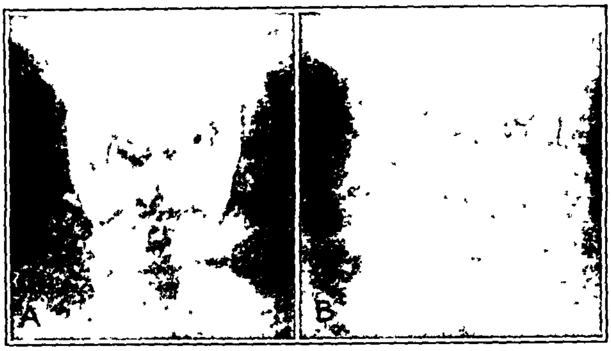

Fig 4 (case 2).—*A*, anterior posterior view of the pharynx, showing the accumulation of barium in the valleculae and pyriform sinuses. *B*, appearance of the pharynx about twenty minutes after injection of the diagnostic ampule.

Case 3.—*History.*—B. C., a man aged 60, had increasing difficulty in swallowing for a period of two months prior to being first seen, Sept. 2, 1943. During this period he had lost 25 pounds (11 Kg.), and about six weeks before entering the hospital he had given up his position as a grocery clerk. He had no regurgitation of liquids through his nose, and he had not vomited. In addition to the difficulty in swallowing the patient had noticed bilateral ptosis of his eyelids and his speech had become nasal in character. There was an increasing tendency for secretions to accumulate in his mouth and pharynx. There also developed a slight weakness in his right leg with a tendency toward foot drop. On examination, there was bilateral ptosis, his speech was nasal in character and chewing and swallowing of solid foods was impossible. He could ingest a slight amount of liquid. The jaw sagged, and there was considerable weakness in the facial muscles, particularly around the mouth. Diplopia was not present.

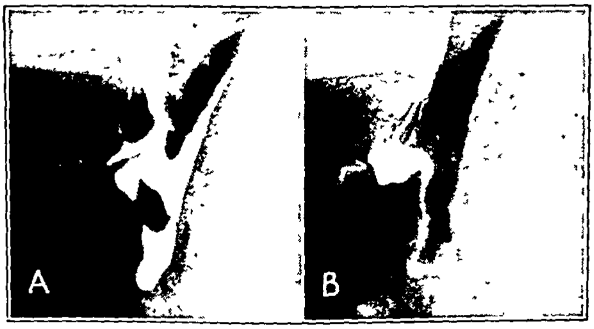

Fig 5 (case 3).—*A*, retention of barium in the pharynx in a patient with well defined dysphagia due to myasthenia gravis *B*, effect of the injection of a diagnostic ampule, showing partial improvement in the swallowing reflex.

Roentgen Examination (Sept. 15, 1943.)—A large amount of barium was retained in the pharynx prior to an injection of a diagnostic ampule of neostigmine (fig 5 *A*). Most of this disappeared twenty minutes after the injection, and the patient's swallowing reflex became relatively normal (fig. 5 *B*).

Subsequent Clinical Course.—The patient was maintained on large amounts of neostigmine bromide by mouth, supplemented by injections of neostigmine methylsulfate before the noon and evening meal. He learned to give the injections himself. Slow but steady improvement was noticed, and within a period of a month he was able to omit one injection a day, keeping his oral medication at a level of twelve tablets in twenty-four hours. He gained 10 pounds (4.5 Kg.) in two months, and at the end of three months was able to give up the injections entirely and gradually reduce the amount of medicine by mouth. Six months after the onset the patient was in a state of complete remission, having no symptoms and not needing any medicine either by mouth or injection He was able to undergo a minor surgical operation at the end of one year and has remained well for a period of slightly over two years

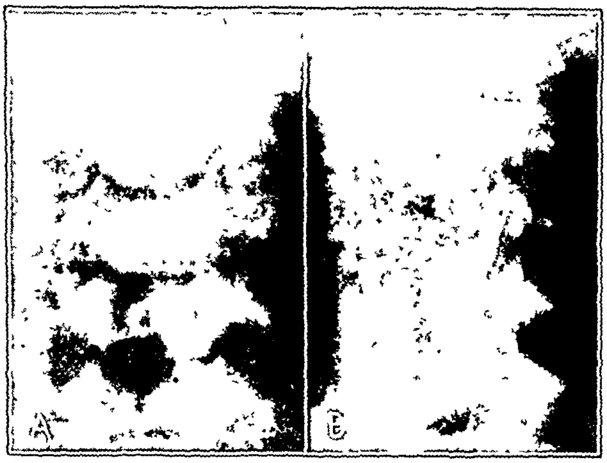

Fig 6 (case 4) —*A*, normal swallowing reflex without retention of barium, in patient well maintained on oral neostigmine *B*, patient without oral neostigmine for thirteen hours, showing defective swallowing reflex with retention of barium

The test may be used as a check of the efficiency of treatment in patients with myasthenia gravis who are being maintained on oral neostigmine. Ordinarily this is not necessary or even desirable, but occasionally one may wish to find out whether the swallowing reflex is still affected even though the patient is free from symptoms. By omitting the oral medication for twelve to twenty-four hours, the test can be done exactly as it is performed as a diagnostic measure. In the following case this was the method used:

Case 4.—*History*—M S., a woman aged 30, began to have dysphagia about three years before her admission to the hospital in February 1943. Subsequently she noted the development of ptosis, diplopia, dysarthria and some general weakness. She was quickly adjusted to a schedule of oral neostigmine. Under treatment she was free from symptoms Her scheduled intake of medicine was omitted for thirteen hours, as a test of its efficiency. At the end of the period the patient had pronounced difficulty in swallowing and her speech was nasal in character.

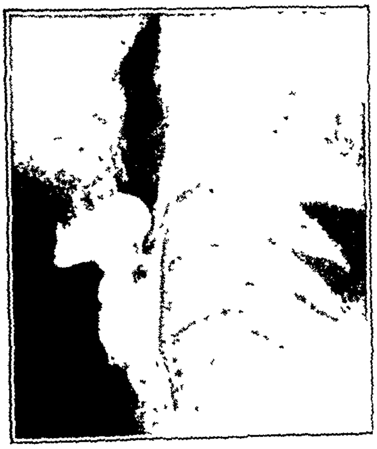

Fig 7 (case 5) —Pronounced retention of barium, just prior to a spontaneous remission, with complete recovery in four months

Roentgen Examination (Feb 4, 1943).—While the patient was well adjusted on oral medication, she was given a swallow of barium and roentgen examination showed no delay in the passage of the barium and *no filling* of the pyriform sinuses (fig. 6 *A*).

Reexamination of the patient who had not taken medicine for thirteen hours showed pronounced difficulty in swallowing. The patient choked during the examination and retained barium in the pyriform sinuses (fig. 6 *B*). Twenty minutes after injection with neostigmine the patient again swallowed in a normal manner and barium was not retained.

Subsequent Clinical Course.—After she left the hospital, the patient was well maintained on oral neostigmine for about two years. She then relapsed and died of respiratory paralysis in another hospital on Aug. 24, 1945.

Although dysphagia may be decided and the patient may show other serious signs of myasthenia gravis, recovery may be rapid soon after the diagnosis is made. The dysphagia, with pronounced retention of barium, may disappear completely in a few months. An example of such a spontaneous remission is as follows:

Case 5.—*History*—C. Y., a woman aged 72, began to have dysphagia six months before entering the hospital on July 18, 1945 Prior to the actual onset, she had noticed intermittent weakness of her pharynx and slight difficulty in swallowing of a transient character for a period of nearly five years The last part of her meal was often difficult to ingest, but her symptoms did not become decided until December 1944. Solid food tended to be retained in her pharynx, and when she attempted to wash it down with fluids, the fluid would be regurgitated through her nose She never had dysarthria In a year's time, she lost about 15 pounds (6 8 Kg.) in weight.

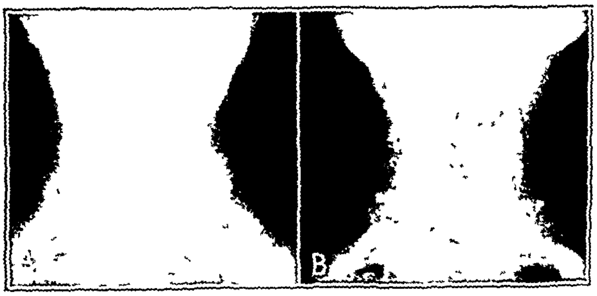

Fig 8 (case 6).—*A*, decided retention of barium in the pharynx and pyriform sinuses in a case of myasthenia gravis with dysphagia *B*, almost complete removal of barium from the pharynx, but with some retention in the pyriform sinuses, after injection with neostigmine in the diagnostic test

On examination, the chief difficulty was in swallowing.

Roentgen Examination (July 18, 1945).—There was well defined paralysis of deglutition, and barium was retained in the pyriform sinuses and valleculae in large amounts (fig. 7). After a diagnostic test with neostigmine, the swallowing reflex was much improved

Subsequent Clinical Course.—The patient rapidly advanced to a spontaneous remission of her symptoms. She only took a small amount of neostigmine for a few days. Her condition improved rapidly, however, and her tablets were soon omitted At the end of about a month she was able to swallow in a normal manner. When seen in November 1945, four months after the testing, she showed no dysphagia and was not taking any medicine.

Not infrequently, the cases of patients suffering from dysphagia as the chief symptom are diagnosed as bulbar palsy. It is rare, however, to have bulbar palsy without atrophy and fibrillations easily observable in the tongue and posterior pharyngeal muscles. Moreover, in this disease the speech is commonly of the "hot potato" type and not the typical nasal speech heard in patients with myasthenia gravis. Patients with myasthenia gravis are unlikely to have dysphagia as the only symptom if a careful history and examination are conducted. One usually finds weakness of the masseter muscles, transient diplopia and ptosis and some evidence of general muscular weakness. Patients, however, may go many months or even years with their disease undiagnosed. The diagnosis may be surprisingly easy when the patient's swallowing reflex is studied before and after an injection of neostigmine. This is illustrated in the following case:

Case 6.—*History.*—H. G., a man aged 71, was first seen in March 1946. Ten months before examination he first noticed weakness of the muscles of his neck, and later, diplopia. Three months after the onset, there was weakness of the masseter muscles and it was necessary for him to hold up his chin with his hand. About the same time dysphagia and dysarthria developed. At times there was great difficulty in swallowing and fluids were regurgitated through his nose.

Roentgen Examination by Dr. A. S. MacMillan (March 28, 1946.)—Roentgen examination revealed decided stasis in the pharynx with retention of barium in the pyriform sinuses before the injection of neostigmine (fig. 8 *A*) After the test the condition of the patient was greatly improved, although some retention was still evident (fig. 8 *B*).

Subsequent Clinical Course.—The patient was adjusted on a schedule of oral neostigmine and improved quickly. Three months after the examination the patient was well maintained on oral medicaments and was almost free from symptoms.

Of the cases chosen to illustrate the diagnostic test it will be noted that 3 of the patients were over 60 years of age and 2 of them over 70. It is in this group, usually first seen by the laryngologist, that the diagnosis is most likely to be missed, for it is the age when degenerative or neoplastic disease is most frequent. The matter should be resolved by the neostigmine test. The test has never been found to be positive in any patients in whom there was reasonable doubt in regard to the diagnosis of myasthenia gravis, and seldom will the test be negative in this disease if the patient has dysphagia as one of the symptoms and is not fully adjusted on a regimen of oral medication.

CONCLUSION

1. If dysphagia is present as a symptom of myasthenia gravis, the response to neostigmine observed under the fluoroscope when the patient is seen in the act of swallowing provides a diagnostic test of considerable value.

2. In no other disease will swallowing be improved as the result of the test. In myasthenia gravis patients with dysphagia, provided they are not fully adjusted on oral neostigmine, will show a prompt and unequivocal response.

3. The amount of the drug to be used is provided in a diagnostic ampule which contains 1.5 mg. of neostigmine methylsulfate and 0.6 mg. of atropine sulfate. The injection is given subcutaneously, and observations are made twenty to thirty minutes later.

4. In a positive test the pyriform sinuses are usually emptied and there is no retention in the valleculae or along the walls of the pharynx. The tone of the pharyngeal muscles may be improved, as seen by increased constriction.

5. A medium thin barium paste should be used, not so thick as to be normally retained either by the pyriform sinuses or along the walls of the pharynx.

6. The response in patients not suffering from myasthenia gravis is nil. These patients, moreover, may have considerable general reaction to the neostigmine due to parasympathetic stimulation. In order to avoid this, atropine sulfate is added to the diagnostic ampule. Certain patients may be particularly sensitive to the neostigmine, and, if so, additional amounts of atropine sulfate should be available at the time of the test.

7. This test for dysphagia is part of the general neostigmine test for myasthenia gravis, but it is particularly valuable in making the diagnosis because of the absence of voluntary control and the clear method of observation by fluoroscopic examination.

ABSTRACT OF DISCUSSION

Dr. Henry W. Newman, San Francisco: Dr. Viets has seen enough cases that he can determine the percentage that have various symptoms. He has stated that in approximately 20 per cent of the cases dysphagia may be the symptom with which the patient presents himself. In other manifestations of myasthenia it is frequently easy to determine by observation the part under stress of function. The myasthenic action of tiring out is quite apparent. Myographic studies can be made and the difficulty easily determined. When the difficulty is in swallowing, frequently there is a great deal of trouble in demonstrating this difficulty, except by the roentgenographic method. This is something which should be done in all patients in whom the diagnosis is not at once apparent. Dr. Viets stated that this enables one to differentiate between myasthenia and degenerative diseases of the nervous system, such as progressive bulbar palsy. The test is also of value in differentiating between various functional nervous complaints, such as hysteria, in which the patient frequently complains of difficulty in swallowing. "There is a ball in my throat which won't go down." This may be purely a hysterical symptom or it may be a presenting symptom of myasthenia gravis. If the person shows difficulty in the swallowing mechanism roentgenographically and this difficulty is cleared up with neostigmine, the physician knows he is not dealing with a neurosis but with myasthenia gravis. Dr. Viets has shown that these patients will get well or relatively well spontaneously or go into a remission which may last a matter of years. One must always bear this in mind in evaluating the reports which have been made in regard to removal of the thymus in this condition. Certainly, the fact that Dr. Viets and others have seen patients from whom presumably a thymoma was removed and who nevertheless have gone downhill in spite of all treatment and in whom at autopsy there has been no evidence of thymus remaining must definitely indicate that aberrant function of the thymus may be one factor in the production of myasthenia gravis. It is not by any means the only factor.

Dr. Victor Goodhill, Los Angeles: I should like to offer information which might be of help in the diagnosis. At the University of Southern California School of Medicine, in the Department of Anatomy, a method of motion picture roentgenography has been devised by Drs. Irving Rehman and Paul Patek. From the Department of Otolaryngology, I have been able to send them a number of patients with various difficulties in swallowing, including several patients with bulbar palsies, several patients with cancers of the hypopharynx and larynx and several tracheotomized patients. It is possible to take these motion pictures under the roentgen ray with barium swallows and to follow beautifully, with slow motion reproduction, the exact operation of the swallowing mechanism. I have seen rather startling demonstrations of palsies of the muscles of deglutition under the controlled guidance of a slow-motion picture roentgenographic reproduction.

Dr. Henry R. Viets, Boston: There are two particular points that I should like to add. One is that the diagnosis of myasthenia gravis is easily made now by injection of the proper amount of neostigmine methylsulfate. This is put up in a special diagnostic ampule which contains the correct amount to use for an adult. If one uses too little, as in the ordinary treatment ampule, one will not get sufficient response, so that some cases will be incorrectly diagnosed on that account.

The second point I should like to make is that the drug neostigmine is an extremely powerful stimulant, particularly in a patient who does not have myasthenia gravis. A normal person taking neostigmine will experience, in some cases, a parasympathetic stimulation of such a degree that he may even collapse. It is on account of this parasympathetic stimulation which occurs in normal persons that atropine is added, and it is advisable to have additional injections of atropine available when this test is made, particularly if the person does not happen to have myasthenia gravis.

DIAGNOSIS OF ANEMIAS IN INFANCY AND CHILDHOOD

CARL H. SMITH, M.D.
New York

The diagnostic features of the anemias in infancy and childhood are influenced by numerous physiologic and anatomic changes which take place within and outside of the hematopoietic system. Alterations of the blood need to be interpreted, therefore, against the shifting background of normal hematologic changes which take place from birth through childhood. During this period the condition of the peripheral blood may reflect the results of the isoimmunization of the mother by fetal blood factors, abnormalities in maternal hematopoiesis, prematurity, the effect of rapid body growth, limitation of reserve bone marrow, reactivation of fetal blood sites and the greater inherent capacity of the hematopoietic system of younger subjects to react excessively to stimuli which would have little effect on an adult.

In this age period the anemias develop insidiously, and diagnosis before specific criteria are established may be difficult. Diagnosis is facilitated by the appraisal of data derived from various sources: history and physical examination, reference to age periods of most frequent incidence, comparison with the normal range of hematic values for each age period, study of the bone marrow by sternal aspiration, the roentgenogram, the hereditary aspects of the disease, careful scrutiny of the blood smear and the therapeutic response to liver, iron and folic acid.

In this presentation the criteria by which a specific disease is diagnosed will be discussed while elaborating more general considerations. Certain especially adapted technical procedures which have been found useful in establishing more precise quantitative data will be described.

HISTORY AND PHYSICAL EXAMINATION

Questions along the broad lines of causation will frequently reveal facts which lead to ready diagnosis. Information should be obtained concerning the onset of pallor, of purpura; the loss of blood from the bowel; infection, including exposure to animal parasites; the use of drugs known to affect hematopoiesis; renal disease; the rapidity of growth; overfeeding of milk with the refusal of solid foods, and the existence of anemia in the mother during pregnancy.

Information in regard to race and nationality is important in the diagnosis of sickle cell anemia and Mediterranean anemia. While sickling of the red blood cells occurs almost exclusively in the Negro race, it has been observed occasionally in the white families which are principally of Mediterranean origin. In Mediterranean anemia the patients are mainly of Greek, of Italian (principally Sicilian and from the Italian peninsula below Naples) or, less frequently, of Syrian origin. Lately a few authentic cases have been recognized among Chinese, Asiatic Indian, Turkish and Egyptian children, and recently Faber and Roth[1] described a case in a Negro girl. There is growing evidence that the trait and mild forms of Mediterranean anemia (familial erythroblastic anemia) occur with greater frequency in this country than published reports have indicated. Since the milder forms may occur in one or both parents born in this country, it is necessary to determine whether any of the grandparents are of Mediterranean origin.

While pallor is frequently misleading as an indication of the degree of anemia, its presence is a valuable diagnostic aid. The history of its onset as obtained from parents is occasionally vague and unsatisfactory, particularly in the chronic forms of anemia. In this connection Wintrobe[2] has pointed out that the physiologic adjustments in chronic anemia may be so efficient that physical activity can be carried out for long periods of time with decidedly lowered hemoglobin levels.

In advanced cases of Mediterranean anemia the skin and facies present a striking diagnostic appearance. The pale, muddy yellow pigmentation of the skin and mongoloid facies produced by changes in the skull bones are characteristic of the established form of Mediterranean anemia. In those instances of aplastic anemia in which the course is prolonged, the increasing pallor is in some instances replaced by a dark pigmentation of the skin which during terminal phases assumes an aspect of bronzing. The value of examination of the skin in diagnosis of anemia is exemplified by a careful history of the exact timing of the development of jaundice. The history of the earlier onset and increasing depth of jaundice in erythroblastosis fetalis differentiates it from the slowly progressing and milder degree of jaundice associated with icterus neonatorum. Visible jaundice at birth and its deepening for a few days is of diagnostic value in those cases of erythroblastosis fetalis in which there is no anemia and in which the number of nucleated blood cells is only slightly increased.

Splenomegaly is commonly found in infants and young children suffering from anemia due to a variety of causes. Enlargement is most noticeable in the diseases associated in some manner with hematic destruction, such as erythroblastosis fetalis, acute hemolytic anemia, familial hemolytic jaundice, sickle cell anemia and Mediterranean anemia. In this group it is not uncommon for an increase in the size of the spleen to occur during periods of pronounced anemia and for shrinking to follow during quiescence, particularly as a result of transfusions. In sickle cell anemia the spleen is most likely to be enlarged in infants and young children and to become progressively smaller and more fibrotic as the patient gets older. In patients with an active form of congenital hemolytic jaundice and in Mediterranean anemia the spleen is enlarged, at times to an excessive size. In patients with the mild

form of both conditions the spleen is either not felt at all or is barely palpable. In young children with anemia of comparable severity the spleen is more likely to be enlarged in Mediterranean anemia than in sickle cell anemia or in congenital hemolytic jaundice. The spleen may be slightly enlarged in anemia due to iron deficiency and in megaloblastic anemia of infancy. It is not enlarged in aplastic or hypoplastic anemia or in the anemia of prematurity.

Except for the anemia associated with infection or with leukemia, lymphadenopathy is not a conspicuous clinical feature of the anemias. Enlarged cervical nodes frequently associated with palpable spleen occur in the anemia due to infection of the upper part of the respiratory passages. The superficial lymph nodes may be slightly enlarged in Mediterranean anemia but not in the other intrinsic anemias. A generalized enlargement of the lymph nodes in the presence of a refractory anemia should arouse suspicion of leukemia. In the early stages of leukemia with leukopenia when no blast cells appear in the peripheral blood the spleen and lymph nodes may not be appreciably enlarged. In these instances the cause of the anemia can be ascertained by the discovery of the blast cells in the bone marrow.

AGE INCIDENCE OF THE ANEMIAS IN RELATION TO DIAGNOSIS

When infection which is responsible for the major number of anemias in younger persons is excluded as an etiologic factor, the remaining blood dyscrasias can be grouped for orientation according to the age periods of their most frequent incidence: newborn, infancy and childhood. The diagnostic features of erythroblastosis fetalis and of hemorrhagic disease of the newborn are apparent at birth or shortly thereafter. The anemia of prematurity, iron deficiency anemia and hypoplastic or congenital aregenerative anemia become noticeable during the earlier months of infancy. Megaloblastic or macrocytic anemia of infancy and hemophilia occur either during the first few months of life or in the older infant. The severe forms of hereditary hemolytic anemias, which consist of Mediterranean anemia, congenital hemolytic jaundice and sickle cell anemia, present themselves initially for diagnosis early in infancy, whereas the manifestations of the moderate forms develop more slowly and are noticed in later infancy or early childhood. Aplastic anemia and congestive splenomegaly (Banti's) disease and other disorders associated with splenomegaly and anemia, such as Gaucher's disease and leukemia, are encountered in childhood. It must be emphasized that the onset of the blood disorders first recognized in older infants and children precedes by a variable period the time when the distinguishing features of the condition become unmistakable.

NORMAL RANGE OF HEMATIC VALUES IN INFANCY AND CHILDHOOD

Hemoglobin Content and Red Blood Cells.—A primary consideration in diagnosis of the anemia is the designation of normal hematic values during the period of growth. A knowledge of the values for hemoglobin and red blood cells at birth and in the early newborn period are essential in the diagnosis of erythroblastosis fetalis, because there may be considerable variation in the clinical and hematologic manifestations of this disease. There is evidence, however, that normal values vary greatly in different areas and that these fluctuations depend in large measure on the race, geographic location and to a great extent on the technic of estimation.

In general the average hemoglobin level on the first day of life may be regarded as 20 Gm. per hundred cubic centimeters of blood, with values ranging from 18 to 22 Gm., and the red count as 5,500,000 per cubic millimeter, with a range from 5 to 6 million. During the first 2 years of life the hemoglobin content normally ranges from approximately 10 to 12.5 Gm. per hundred cubic centimeters of blood, with an average value of 11 Gm. Between 3 and 5 years of age it ranges from 12.5 to 13 Gm., and between 5 and 10 years, from 13 to 13.5 Gm.; during puberty it rises gradually to the adult value of 14.5 Gm. per hundred cubic centimeters. A count of 4 million red cells per cubic millimeter of blood may be regarded as the lower limit of normal for the older infant and child. In normal newborn infants the number of nucleated red cells in the first few days of life ranges from 3 to 10 per 100 white blood cells.

Volume of Packed Red Cells.—In all anemias the measurement of the volume of packed red blood cells by the hematocrit constitutes an important and essential guide for diagnosis and therapy. This determination reflects the total mass of cells in a unit volume of blood and has proved of fundamental value in the study of all anemias, in which considerable alterations occur in the size, shape and thickness of the red blood cells. It has the advantage of being reliable and least subject to error in quantitative interpretation. In iron deficiency anemia, for instance, the extremely low hematocrit measurement reflects the state of anemia more accurately than does the more moderate reduction in the number of red blood cells. Also in the asymptomatic person with the trait of Mediterranean anemia the volume of packed red cells frequently remains at the same level in spite of wide fluctuations in the number of red cells.

For measuring the volume of packed red cells with the use of blood from the finger, the method described in previous publications[3] has continued to prove reliable; it is particularly useful in infants and children, in whom repeated venipuncture is undesirable. The values secured with this method coincide with those obtained with venous blood.

Because of the variations noted in available studies, it is difficult to state the optimum packed cell volume for different age groups. As a working basis, a hematocrit reading of 36 per cent constitutes the lower limit of normal for infants and children and one of 40 per cent, the minimum for older groups.

The Fragility Test.—The resistance of the red corpuscles to varying dilutions of hypotonic solution of sodium chloride constitutes an important laboratory procedure in the diagnosis of the anemias and is especially useful in the differentiation of the hemolytic group. The response of blood cells in the fragility test does not necessarily reflect their reaction within the circulating blood, where conditions of isotonicity prevail. The resistance of the red cells to hemolysis in the fragility test depends undoubtedly on a number of intrinsic factors, which involve the structure and properties of the cell envelope. It constitutes, however, a useful gross index of the relative thickness of the major number of red cells in the sample of blood to be tested. If the red cell envelope is small in relation to its volume, as in the thick red cells or spherocytes of familial hemolytic jaundice, the resistance is decreased. Increased resistance to hemolysis is noted when the bulk of red blood cells possess relatively large surfaces in comparison with their substance, as occurs in the thin red cells of Mediterranean anemia and in iron deficiency anemia. Sickle cells are also more resistant to hypotonic saline solutions than are normal cells.

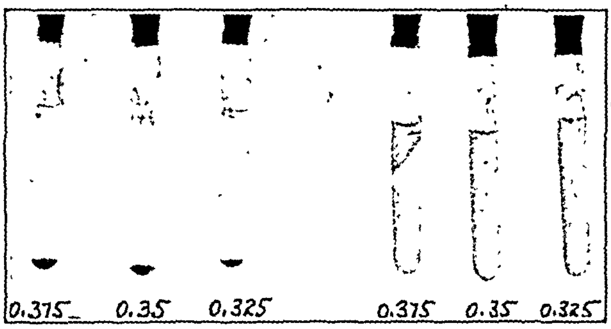
[3] (a) Smith, C. H.: A Method for Determining the Sedimentation Rate and Red Cell Volume in Infants and Children with Use of Capillary Blood, Am. J. M. Sc. **192:** 73 (July) 1936. (b) Sedimentation Rate in Nutritional Anemia of Infants and Children, Am. J. Dis. Child. **56:** 510 (Sept.) 1938.

Increased fragility of the red cells in hypotonic solutions of sodium chloride as compared with the fragility of normal blood occurs in congenital hemolytic jaundice and occasionally in acute hemolytic anemia associated with infection and ingestion of drugs. Decreased fragility with complete hemolysis in solutions below 0.3 per cent sodium chloride characterizes the blood of sickle cell anemia, mild and severe forms of Mediterranean anemia and iron deficiency anemia.



Screening test for erythrocyte fragility employing blood from the finger. The three tubes on the left contain blood from a person with the trait of Mediterranean anemia and show decreased fragility. The corresponding tubes on the right contain blood from a control and show normal hemolysis.

In studying large groups of patients suspected of having one of the forms of Mediterranean anemia several technical difficulties were encountered, which interfered with the frequent performance of fragility tests, especially in several members of a family. The difficulties involved the preparation of a large number of tubes containing serial dilutions of hypotonic solution of sodium chloride, the use of venous blood in small children and the need for a control in each period.

A screening test was therefore devised utilizing blood from the finger and three dilutions of hypotonic solution of sodium chloride, which experience had shown to offer information of a decisive diagnostic character. These were the tubes containing 0.375 per cent, 0.35 per cent and 0.325 per cent of sodium chloride. The method as here outlined is not meant to replace the routine fragility test but was devised solely as a gross method in screening out large numbers of patients suspected of having Mediterranean anemia. With the use of blood from the finger controls are readily available, and in normal persons the degree of hemolysis in the three tubes is as follows: with 0.375 per cent solution of sodium chloride, 3 plus; with 0.35 per cent, 3 or 4 plus, and with 0.325 per cent, 4 plus. Two or three drops of blood from the finger depending on the severity of the anemia, are obtained by deep puncture and added to each of the three tubes, each of which contain 2 cc. of solution of the prescribed concentrations of sodium chloride. After thorough mixing of blood and solution, the tubes are allowed to stand in a refrigerator until sedimentation has occurred. The degree of hemolysis and the residue of unhemolyzed red cells are compared with the same factors in the blood of a normal control treated in the same manner. If any clotting occurs the tube is centrifuged at low speed for a few minutes and the degree of hemolysis in the supernatant fluid is compared with that found in the corresponding tube of the control.

In seventy-five comparative tests with finger and with venous blood the extent of hemolysis in each of the tubes closely approximated that in the corresponding tube. When any discrepancy occurred venous blood was found to be slightly more fragile than finger blood. The usefulness of this procedure has also been demonstrated in a small group of cases which included congenital hemolytic jaundice, sickle cell anemia and iron deficiency anemia. The results with this method will be reported more fully later.

The Reticulocyte Count.—The reticulocyte count reflects the state of activity of the bone marrow; hence this determination provides a useful guide in the diagnosis of both deficiency and hemolytic anemias and in gaging the response to treatment. Normally from 0.5 to 1.5 per cent of the red blood cells are reticulated, and levels below 0.5 per cent represent an inactive bone marrow. A persistent depression in the percentage of the reticulocytes in spite of treatment occurs in aplastic and in hypoplastic anemia. In anemia due to a deficiency a reticulocyte response from previously low levels follows appropriate treatment. In the hemolytic anemias the values for reticulocytes are consistently elevated, and the high levels which are sustained prior to and without treatment represent intensified activity of the bone marrow. A simplified procedure previously described [8b] has been employed, which has been adapted from standard methods and requires no preliminary preparation of slides or other devices.

Icterus Index.—Blood destruction may be gaged by the level of the biliary pigments in the plasma and by the quantitative estimation of the urobilin in the stools. Intensity of the pigmentation of serum is readily measured by the icterus index, which usually ranges from 4 to 6. In hemolytic anemias the values range between 15 and 25. A greatly elevated icteric index points to hepatic damage and biliary obstruction rather than to jaundice due to hematic destruction alone.

EXAMINATION OF THE BONE MARROW BY STERNAL PUNCTURE

Investigation of the bone marrow by sternal puncture constitutes an invaluable laboratory aid in association with a careful examination of the peripheral blood. Information as to the normal range for the total nucleated cell count, the differential percentages for each type of cell, the variability in different age periods and the extent of individual fluctuations in bone marrow obtained by sternal aspiration is still limited. Despite these restrictions certain qualitative and gross quantitative alterations can be ascertained and a rough estimate made of hypoplasia or hyperplasia in the bone marrow and of the predominance of one or more types of cells.

Normal Bone Marrow.—The figures in table 2 represent the approximate range and average values of the cellular elements which one may expect to find in samples of the bone marrow obtained from normal infants and children. The higher lymphocytic percentages have been noted in normal infants beyond the neonatal period.

Bone Marrow in the Anemias.—The individual cellular constituents in the bone marrow are in such close proximity to each other that it is difficult to affect one element independently of the other. This total stimulation is best observed in the hemolytic anemias and most regularly in acute hemolytic anemia. In the latter, regeneration of the red blood cells is associated with an increase in the number of granulocytes and platelets. The reverse occurs in aplastic anemia, in which values for the three types of blood cells are depressed simultaneously. However, other factors must operate in addition to anatomic proximity, since involvement of a single type of cell may occur. This is illustrated in hypoplastic anemia, in which the production of red blood cells is inhibited without equal depression of the other cellular elements. Similarly, selected hyperplasia occurs in iron deficiency anemia and in chronic loss of blood, in which the normoblasts and their immediate precursors alone are primarily increased.

In the group of hemolytic anemias, which comprise congenital hemolytic jaundice, acute hemolytic anemia, sickle cell anemia and Mediterranean anemia, the bone marrow is hyperplastic and there is an increased proliferation of normoblasts and to a lesser extent of erythroblasts. Granulopoiesis may be active especially in acute hemolytic anemia. In iron deficiency anemia and in chronic hemorrhagic anemia the bone marrow is similarly hyperplastic; values for normoblasts are greatly elevated, but granulopoiesis is normal. In acute hemorrhage, however, the activity of the myeloid elements is also increased. The increase of the nucleated red cells in these disease processes in excess of 50 per cent of all the nucleated elements in the marrow constitutes an important diagnostic feature.

Aplastic anemia is associated with hematic observation of profound anemia, leukopenia, neutropenia and thrombocytopenia. The bone marrow shows a progressive decrease in cellularity, and there is a sharp reduction in the myeloid elements, megakaryocytes and nucleated red cells with a relative increase in normal lymphocytes. Occasionally acute lymphoblastic leukemia in the leukopenic stage may simulate aplastic anemia, and diagnosis is difficult without histologic examination of the bone marrow. Sternal aspiration in patients with leukemia will reveal a cellular bone marrow in which the normal nucleated elements are replaced by lymphoblasts and lymphocytes. With the progressive reduction in the number of platelets, hemorrhages occur in aplastic anemia which may simulate thrombocytopenic purpura. In the latter disease the bone marrow reveals hyperplasia of the megakaryocytes with values ranging from 200 to 300 per cubic millimeter.

Hypoplastic anemia differs from aplastic anemia in that the formation of red blood cells is depressed without equal involvement of the granulocytes or platelets. Aspiration of the bone marrow reveals pronounced reduction in the numbers of nucleated red cells as well as an increase in the numbers of primitive cells, or hematogones, and of eosinophilic leukocytes. The bone marrow in macrocytic or megaloblastic anemia of infancy[4] reveals a megaloblastic type of erythropoiesis and changes in the granulocytes resembling those observed in pernicious anemia.

THE ROENTGENOGRAM IN DIAGNOSIS OF HEMATIC DYSCRASIAS

The greater value of the roentgenogram in the diagnosis of hematic dyscrasias in earlier periods of life can be related to the developmental features of the bone marrow. Only with the appearance of nonfunctioning yellow marrow in the older child and its extension in the young adult is a potential reservoir created for the formation of blood when the demand for hematic regeneration is increased. In early infancy, however, the need for increased formation of blood arising from anemia due to infection or associated with specific hematic diseases may necessitate the reactivation of extramedullary fetal sites. When there is need beyond this for the formation of blood, the marrow expands by absorption or atrophy of bone trabeculae and of the cortex, and the visualization of these changes in the roentgenogram is utilized in diagnosis.

Leukemia may be difficult to distinguish from other hematic dyscrasias in the stage when anemia is associated with leukopenia and minimal enlargement of the spleen and lymph nodes. The roentgenogram fre-

TABLE 1.—*Significant Normal Values in Diagnosis of Anemias of Infany and Childhood*

Hemoglobin	1st day	20 Gm. (18 to 22 Gm.)
	2 weeks	17 Gm.
	1st 2 years	11 Gm. (10 to 12.5 Gm.)
	3 to 5 years	12.5 to 13 Gm.
	5 to 10 years	13 to 13.5 Gm.
	10 years to puberty	13.5 to 14.5 Gm.
Red blood cells	1st day	5,500,000 (5 to 6 million)
	2d week	5,000,000
	Older infant and child	4,000,000 per cu. mm. lower limit of normal
Nucleated red cells	Average at birth ranges from 3 to 10 per 100 white cells	
Reticulocytes	0.5 to 1.5%; (below 0.5% in aplastic and hypoplastic anemia; increased in hemolytic anemia; in deficiency anemia rise from low to high levels with treatment)	
Volume of packed red cells	Infants and children	30% is lower limit of normal
	Older age groups	40% minimum
Icterus index	Normal, 4 to 6 units; (hemolytic anemias, 15 to 25%)	
Fragility test	Normal range 0.425 to 0.325% sodium chloride; (increased fragility in congenital hemolytic jaundice and in some cases of acute hemolytic anemia; decreased fragility in sickle cell anemia, Mediterranean anemia and in iron deficiency anemia)	

TABLE 2.—*Relative Number of Nucleated Cells in Normal Bone Marrow (Sternal Aspiration)*

Total nucleated cell count approximately 100,000 to 150,000 per cu. mm.

	Range, %	Average, %
Myeloblasts	1 to 5	2
Myelocytes (including promyelocytes)	10 to 25	20
Nonsegmented polymorphonuclears (including metamyelocytes)	15 to 30	20
Segmented polymorphonuclears	5 to 30	25
Lymphocytes	5 to 25	13
Nucleated red cells (principally normoblasts)	15 to 30	20
Plasma cells	Occasional	
Monocytes	Occasional	
Reticulum cells	Occasional	
Hematogones	Occasional	
Megakaryocytes	10 to 35 per cu. mm.	

---

[4] Zuelzer, W. W., and Ogden, F. N.: Megaloblastic Anemia in Infancy: A Common Syndrome Responding Specifically to Folic Acid Therapy, Am. J. Dis. Child. 71:211 (March) 1946.

quently throws light on the underlying pathological process in leukemia, disclosing generalized or local rarefaction, focal areas of absorption of the bone and of periosteal elevation. The extensive erythrogenesis is seen in Mediterranean anemia, familial hemolytic jaundice and sickle cell anemia. Pronounced skeletal changes appear with greatest regularity in Mediterranean anemia and similar changes but to a lesser extent are observed in the other members of this group. The roentgenogram in Mediterranean anemia reveals the evidence of extreme hyperplasia of the bone marrow by osteoporosis, thinning of the cortex, trabecular atrophy, coarse reticulation with regeneration of new bone, which is a later development in the disease, and thickening of the skull. Lateral views of the skull show an enlarged diploic space which is finely granular or mottled or striated. The vertical striations give the appearance of "hair standing on end," which seems to extend beyond the outer table. The earliest signs are observed in the small bones, particularly in the metacarpals and metatarsals, and reveal osteoporosis and expansion of the medullary cavities, producing a rectangular instead of the normal concave appearance. The inital osteoporotic process which occurs in infancy and early childhood is succeeded by osteosclerosis, in which new bone is formed and is represented in the roentgenogram by trabeculation and coarse reticulation. Osteosclerosis with cortical thickening in the large bones constitutes an outstanding feature of sickle cell anemia in adults, although its evolution from a previous osteoporotic phase has infrequently been noted.

TABLE 3—*Diagnostic Features of the Bone Marrow (Sternal Puncture) in Anemias of Infancy and Childhood*

Hemolytic group	
Erythroblastosis fetalis	Hyperplastic marrow with increase of nucleated red cells—chiefly normoblasts; granulopoiesis may also be active
Congenital hemolytic jaundice	
Sickle cell anemia	
Mediterranean anemia	
Acute hemolytic anemia	
Iron deficiency anemia..	Hyperplastic marrow with increase in normoblasts; granulopoiesis unchanged
Hemorrhagic anemia	Hyperplastic marrow with increase in nucleated red cells, chiefly normoblasts; granulopoiesis active in acute hemorrhage and unchanged in slow and chronic loss of blood
Megaloblastic anemia of infancy .	Pattern similar to pernicious anemia in relapse, megaloblastic type of erythropoiesis and changes in granulocytes resembling pernicious anemia
Aplastic anemia............	Usually decreased cellularity to acellular; sharp reduction in myeloid elements, megakaryocytes and normoblasts and increase in lymphocytes
Hypoplastic anemia...	Hypoplastic marrow with pronounced depression affecting normoblasts mainly; primitive cells (hematogones) and eosinophils increased
Lymphatic leukemia	Replacement of normal nucleated elements by lymphoblasts and lymphocytes
Thrombocytopenic purpura. ...	Moderate hyperplasia of marrow with increase in megakaryocytes

HEREDITARY FACTORS AS AN AID IN DIAGNOSIS

The accurate diagnosis of diseases of the blood in younger subjects frequently requires a consideration of hereditary factors. In certain of the hematic diseases a clue to causation and diagnosis is obtained by a search for similar hematologic abnormalities in the mother, by an investigation of the possible interaction of immunologic factors between mother and fetus which affect hematopoiesis and by a study of the blood of parents and siblings of the affected child for the presence of the trait.

The diagnosis of hypochromic microcytic anemia in an infant between the age of 3 and 6 months on the basis of inadequate storage of iron in fetal life is suggested by a history of iron deficiency in the mother during pregnancy. Congenital thrombocytopenic purpura in infants may be considered when the disease has been present in the mother. Occasionally, thrombocytopenia in the mother has not been associated with serious clinical manifestations and this condition has been discovered while investigating the source of purpura in the infant.

Probably the most important element in the diagnosis of erythroblastosis fetalis depends on a genetic study of the Rh blood factor in the infant and its parents. Typing of the blood for the Rh factor has become an essential diagnostic procedure. In the majority of cases the red cells of the father and of the infant possess the Rh factor and the mother lacks it. In the smaller group of Rh positive mothers, the Hr and the A and B agglutinogens may represent the responsible immunizing agents.

Sickle cell anemia, hemolytic jaundice and Mediterranean anemia are familial diseases in which the hereditary trait may be recognized by appropriate hematologic studies. The constitutional nature of these diseases is reflected in the comparatively high incidence in members of the same family.

The diagnosis of these diseases in a child with an obscure anemia of moderate severity can often be made earlier in its course and useless therapy avoided by the detection of the trait in the parents and siblings. In Mediterranean anemia, for instance, the most important element in the diagnosis of the milder form is the discovery of qualitatively similar alterations in the blood of other members of the same family. These persons are asymptomatic and are either mildly anemic or without anemia. Regardless of the hemoglobin level their blood shows hypochromic macrocytes, stippled erythrocytes, polycythemia, increased resistance of the red cells to hemolysis in hypotonic solutions of sodium chloride and, less frequently, target and oval cells. The presence of basophilic stippling may be so pronounced in the mild form of the disease as to confuse the condition with lead poisoning. On the basis of previous studies [5] and of an investigation now in progress the evidence is conclusive that in every family with a child severely affected with Mediterranean anemia and requiring periodic transfusions of blood both parents revealed evidences of the disease. As a corollary the important principle may be affirmed that the designation of a hematic dyscrasia as a moderate or severe form of Mediterranean anemia should not be made unless at least one of the parents shows the trait of the disease.

---

[5] Dameshek, W.: Familial Mediterranean Target Oval Cell Syndromes, Am. J. M. Sc. **205:** 643 (May) 1943. Smith, C. H.: Familial Blood Studies in Cases of Mediterranean (Cooley's) Anemia, Am. J. Dis. Child. **65:** 681 (May) 1943. Valentine, W. N., and Neel, J. V.: Hematologic and Genetic Study of the Transmission of Thalassemia, Arch. Int. Med. **74:** 185 (Sept.) 1944.

Rundles and Falls[6] recently described an anemia affecting the male members of two families of non-Mediterranean origin which was transmitted by females without anemia. Many of the latter had large spleens, and examination of their blood revealed minor abnormalities of the red cells.

DIAGNOSTIC CHARACTERISTICS OF THE BLOOD SMEAR

The examination of the blood smear represents the most direct means for observing the effect on morphology of the factors involved in the pathogenesis of a particular form of anemia In enumerating the changes in the blood cells it should again be emphasized that except for sickle cells and spherocytes there are no specific cells which may be considered pathognomonic of a particular disease. Target cells, oval cells, hypochromic macrocytes and basophilic stippling appear in certain stages of many anemias and therefore cannot be regarded as a specific hematologic feature of a single disease. They are of diagnostic value only when they are considered in conjunction with pertinent information obtained from other sources When anemia results from direct bone marrow depression such as occurs in aplastic and hypoplastic anemia or the marrow cell displacement of leukemia, the red cells are both normochromic and normocytic, and anisocytosis, poikilocytosis and achromia are minimal

In erythroblastosis fetalis, the acute phases of congenital hemolytic anemia, sickle cell anemia, Mediterranean anemia, acute hemolytic anemia and acute posthemorrhagic anemia, the blood film reveals certain common features These reflect increased activity of the bone marrow and include reticulocytosis, nucleated red blood cells, leukocytosis, increased granulocytes, immature myeloid cells and in certain instances (acute loss of blood and acute hemolytic anemia) an elevation in the number of platelets.

The hematic observations that characterize each form of anemia are summarized in table 4 Occasionally the blood films in well defined conditions resemble each other so closely that corroborative evidence from auxiliary sources is required to establish a diagnosis This overlapping is exemplified in certain children with sickle cell anemia in whom the typical cells are demonstrated with difficulty in the fixed smear or with sealed preparations of fresh blood. In the anemic patient with this disease the smear reveals target and oval cells, numerous hypochromic macrocytes and occasional stippled cells When sickle cells are absent, differentiation of this disease from Mediterranean anemia at a comparable stage is difficult Reexamination with various technics to demonstrate sickling and study of the blood of other members of the family for the distinguishing features of either disease may be necessary to separately classify the two conditions

THERAPEUTIC RESPONSE AS AN AID IN DIAGNOSIS

The insidious onset of many of the anemias of early life renders their diagnosis difficult before specific criteria are established Until the important features have developed, the response to a therapeutic agent often serves to eliminate certain conditions and focus attention on others Since the low hemoglobin value is the outstanding feature of the anemias in early life, the observed response to a therapeutic trial with an iron salt constitutes an ideal preliminary procedure for purposes of differential diagnosis. For example, when iron in sufficient dosage is administered to an infant or young child with anemia of moderate severity, the absence of a reticulocyte response and a failure of the hemoglobin to return to normal values within three to four weeks suggest continued activity of an acute or chronic infection or of some other exogenous factor or that the diagnosis of anemia on a deficiency of this mineral alone is to be questioned By the employment of this principle, cases of Mediterranean anemia have been uncovered in early infancy when the clinical, [illegible] hematologic features were still [illegible], anemic syndromes resistant to therapy with liver and iron suggest the possibilities of aplastic or of hypoplastic anemia On the other hand a satisfactory response to folic acid or to liver extract in an infant with a macrocytic anemia contributes important confirmatory evidence for the diagnosis of megaloblastic anemia[4]

Table 4—*Diagnostic Features of the Blood Smear in Anemias of Infancy and Childhood*

Erythroblastosis fetalis	Hyperchromic macrocytes, nucleated red blood cells
Hemorrhagic anemia *.	Acute blood loss, normochromic and normocytic red blood cells, chronic blood loss; hypochromic microcytes
Iron deficiency anemia	Hypochromic microcytes, pronounced central pallor of red blood cells, poikilocytes
Anemia of prematurity.	Early normocytic and normochromic red blood cells; later hypochromic microcytes
Megaloblastic anemia of infancy	Extremely large macrocytes, microcytes, occasional nucleated red blood cells, abnormal neutrophils
Aplastic and hypoplastic anemia	Normochromic and normocytic red blood cells
Congenital hemolytic anemia ..	Spherocytes and large number of reticulocytes
Sickle cell anemia	Sickle cells, target and oval cells, hypochromic macrocytes
Mediterranean anemia †	
Severe type	Extremely large, thin hypochromic macrocytes; nucleated red blood cells, pronounced poikilocytosis and anisocytosis
Mild type or trait	Hypochromic macrocytes, basophilic stippling, polycythemia, target and oval cells

* This applies to phases of hemorrhagic disease of the newborn, hemophilia, thrombocytopenic purpura, to less common hemorrhagic disorders and to nonspecific conditions associated with loss of blood

† In both types the red blood cells show increased resistance to hemolysis in hypotonic solutions of sodium chloride

SUMMARY

While many of the anemias of infancy and childhood do not differ greatly from those of the adult, their diagnosis may be attended with difficulty because of peculiarities in this age period The anemias in early life develop insidiously, and diagnosis may be uncertain before specific criteria are established Alterations in the blood need to be appraised in the light of the residual effects of fetal and maternal influences on hematopoiesis and of normal changes incident to growth and development Many of these complexities may be resolved and diagnosis facilitated by coordinating the information obtained from the sources which were described in this paper. The detection of hematic disturbances requires a careful history and the use of simple instruments and technics; and the collection of data and their interpretation lie within the province of every medical practitioner.

PATHOGENESIS OF ANEMIA IN INFANCY AND CHILDHOOD

WOLF W. ZUELZER, M.D.
Detroit

Anemia is a pathologic state characterized by a decrease in the amount of hemoglobin per unit volume of circulating blood and resulting in a reduction of the oxygen-carrying power of the blood. Many details regarding the genesis of anemia remain to be settled, but it is clear that the various causative factors capable of producing the anemic state must operate through a few basic mechanisms. An understanding of these mechanisms is essential for the interpretation of blood pictures and for the rational treatment of the anemias of all age groups. The peculiarities of the anemias of infancy and childhood are due not to fundamental differences in the pathogenic mechanisms but to the peculiarities of the infantile organism itself, especially growth and metabolism, nutrition and susceptibility to infection, which modify and favor the development of anemia. While stressing the significance of these special features, a discussion of the pathogenesis of the anemias of infancy must be based on principles applicable to anemia in general.

The blood, more specifically the circulating hemoglobin, may be compared to a reservoir in which a constant level is maintained by regulatory mechanisms which govern the intake and outflow. The intake is determined by the production and release of hemoglobin-containing cells by the marrow organ, which is the only normal source of supply in extrauterine life. The outflow represents destruction and removal of erythrocytes from the circulation with subsequent breakdown of hemoglobin in the reticuloendothelial system, especially the spleen. Under physiologic conditions the production and destruction of hemoglobin are balanced, and in adult life both the size and the level of the reservoir remain constant. In childhood, especially in infancy, however, the production of hemoglobin must not only replace physiologic losses but also furnish new material as the total blood volume increases with the rapid growth of the body, so that the absolute size of the reservoir is greatly expanded while its level remains nearly constant. In the anemic state the level falls because the regulatory mechanisms fail. In the last analysis anemia is always the result of either diminished production of hemoglobin by the marrow or excessive loss of hemoglobin from the circulation or a combination of both. For the purposes of this discussion the two fundamental mechanisms will be considered separately.

DIMINISHED PRODUCTION OF HEMOGLOBIN BY THE MARROW

The role of the marrow in the production of hemoglobin may be viewed under the aspects of cellular regeneration and the synthesis of hemoglobin. Erythrocytes are formed by mitotic division of nucleated precursor cells—erythroblasts—at different levels of cellular development. In the process of maturation the erythroblasts synthesize hemoglobin and cease mitotic activity. The majority of these elements lose their nuclei, pass into the reticulocyte stage and are then ready for delivery into the circulation. The regeneration of erythrocytes is a delicately integrated process, which normally operates far below the maximum capacity of the system. The known facts support the view that this process is regulated within certain limits by the supply of oxygen and that relative anoxia stimulates mitotic division of erythroblasts, while an abundant oxygen supply seems to have the opposite effect.

In fetal life oxygen tension is low and erythropoiesis is highly active. In early infancy a quantitative reduction in erythroblastic regeneration takes place, apparently in response to the improved oxygenation following the change from placental to pulmonary ventilation. This adjustment falls into a period of rapid growth with expansion of the blood volume, which tends to dilute the circulating hemoglobin. The combination of these two factors, decrease in the rate of erythropoiesis and increase in the volume of blood accounts for the relatively low hemoglobin level of the normal infant which is spoken of as the physiologic anemia of infancy. The more pronounced anemia of prematurity is due to an accentuation of these same factors. The growth rate and expansion of blood volume is relatively greater than in the full term infant. The oxygen supply to the tissues of the premature infant may be assumed to be greater than that available to a fetus of comparable conception age. Moreover, the hypothermia and inactivity of such infants suggest a low rate of consumption of oxygen. One would therefore expect an inactive erythropoiesis, and this is borne out by actual studies of the marrow.[1] Blood formation in the premature infant is even less active than that in the full term infant. The anemia of prematurity, like the physiologic anemia of early infancy, is not due to some deficiency but may be considered as the result of these adjustments which are physiologic for the premature infant, as far as anything can be called physiologic in these patients. This view is supported by the observation made repeatedly in the laboratory of the Children's Hospital of Michigan that hemolytic or hemorrhagic episodes which produce a definite demand on the marrow are followed by hyperplasia of the marrow and reticulocytosis of the peripheral blood even in premature infants. This observation indicates that the marrow can respond if the proper stimulus is provided. It should be clear that the administration of iron cannot influence the early phases of the anemia of prematurity although it later can prevent the iron deficiency anemia to which the premature infant is subject after the third month.

The view that the rate of regeneration of the red blood cells is related to the available supply of oxygen is supported by the observations in hypothyroidism, in which the consumption of oxygen in the tissues is abnormally low. The anemia of myxedema is associated with hypoplasia of the bone marrow (a reduction in the number of cell divisions), which has been interpreted as an adjustment to the low oxygen consumption of the hypothyroid state.[2] It is possible that the anemia often seen in scurvy is likewise related to decreased consumption of oxygen, because lack of ascorbic acid interferes with the oxidative process in the body and because hypoplasia of the marrow has been noted in scurvy.[3] However, loss of blood and iron deficiency

usually complicate infantile scurvy, and the evidence in regard to the anemia of scurvy is as yet conflicting.[4]

Reduction in the supply of oxygen to the marrow is followed by an increase in the rate of regeneration of the red blood cells. It is immaterial whether the anoxia is brought about by decreased atmospheric oxygen pressure, by increased consumption of oxygen in the rest of the body, by circulatory conditions, by impairment of pulmonary ventilation or by anemia. Anoxia is the common denominator of these states and may be considered as the physiologic stimulus for regeneration of the red blood cells. It is doubtful whether erythropoiesis can be stimulated in any other way except through the mechanism of marrow anoxia. At least it has not been shown that normal marrow under normal oxygen tension can be stimulated to increase the production of red blood cells.

Anemia, then, is in itself a stimulus for the marrow. This is illustrated by the changes which follow acute loss of blood. The anemia causes a decided increase in the number of cell divisions among the erythroblasts, i. e., the marrow becomes hyperplastic. As newly formed cells mature and reach the reticulocytic stage they enter the blood, the anemia is alleviated, the oxygenation of the tissues improves and the marrow response subsides. In the previously normal person this sequence of events occurs without any form of therapy. If anoxia of the marrow is prevented or relieved by blood transfusion the response is abolished or proportionately diminished.

The effect of excessive destruction of the blood on the activity of the marrow is the same as that of sudden loss of blood. However, if blood destruction is continuous and severe, as in chronic hemolytic anemias, even maximal activity of the marrow cells may not fully compensate for the loss of hemoglobin and the anemia may persist. If the degree of hematic destruction can be reduced, as may be the case after a splenectomy has been performed, the activity of the marrow decreases as the hemoglobin approaches normal levels.

Such compensatory adjustments require a normally functioning marrow organ. Often, however, impairment of erythropoiesis itself is the primary factor in the development of anemia, and in that case the anoxic stimulus cannot be effective until conditions necessary for normal functioning of the marrow are restored.

This is illustrated by the true marrow deficiency states, in which factors essential for the normal functioning of erythroid cells are lacking. Experimentally a number of such factors have been demonstrated, but thus far only two have proved of practical clinical significance. One is an antianemic principle often referred to as erythrocyte maturation factor, contained in liver and according to recent studies also in folic acid[5] and perhaps identical with the latter. If this factor is not available to the marrow the erythroblasts become abnormal in structure and function. In these pathologic cells, which are generally called megaloblasts, the delicate mechanism of mitotic division is affected.[6] Multiplication is restricted mainly to the most primitive precursor cells. This derangement in the regulation of mitotic activity leads to the apparent paradox of marrow hyperplasia with hypoplasia of the blood, or anemia; few of these primitive megaloblasts mature, and their long maturation period means delay in their delivery to the blood. Such cells as enter the circulation are large because they represent end stages in the development of large primitive cells; hence, anemias of this type are usually macrocytic. Pernicious anemia, the classic example of a deficiency in antianemic principle, seldom occurs in infants[7] and is extremely rare in children. Recent studies of marrow patterns, however, have shown that a temporary deficiency of the antianemic principle is fairly common in infancy. The term megaloblastic anemia has been proposed for this condition.[8] It can arise as the result of dietary deficiency as in so-called goat's milk anemia and also apparently through interference with absorption or utilization of antianemic principle on the basis of infection. Megaloblastic anemia is occasionally seen in children with celiac disease as one of the secondary deficiency states associated with faulty absorption by the gastrointestinal tract. If the missing antianemic factor, whether it be liver principle or folic acid, is supplied, cellular regeneration quickly returns into normal channels, the stimulus of the anemia can lead to an effective response by the marrow and mature cells are again produced in adequate numbers.

Iron deficiency states have a somewhat different effect on the marrow. Iron is an actual building stone of the hemoglobin molecule. The erythrocytes which are produced when adequate amounts of iron are not available to the marrow cells are small and hypochromic, because they contain less than their normal complement of hemoglobin.[9] The erythroid marrow may respond to the anemia and become hyperplastic, but the hemoglobin content of the cells and the hemoglobin level of the blood continues to fall. Soon the red blood cell count also falls, because the hemoglobin-deficient erythroblasts do not mature properly and as a result fewer and fewer cells reach the circulation. When iron is made available, the synthesis of hemoglobin can proceed and the cells again mature in normal fashion.

Obviously iron can be effective only where an iron deficiency of the marrow exists. This occurs principally after exhaustion of the storage iron in the tissues. The preponderance of iron deficiency anemia in infancy is related to the state of this reserve. The storage iron is scarcely affected by the loss of iron through excretion, which is negligible. The iron liberated in the breakdown of hemoglobin can be used over and over for the formation of blood. In the adult the blood volume and total hemoglobin mass is constant and the iron reserves of the tissues are seldom drawn on except after an actual loss of iron from the body, as in hemorrhage. In the infant the rapid growth of the blood volume requires a considerable increase in total hemoglobin if adequate levels are to be maintained. It has been aptly said that the infant bleeds into its own increasing blood volume.[10] Since the milk diet of early infancy is poor in iron it follows that the infant must draw on storage iron for blood formation and live, as it were, on its capital reserve of iron. The smaller the initial deposit and the greater the rate of withdrawal, i. e., the growth rate, the more likely it is that anemia will develop. The premature infant who fails to receive the deposits of iron normally transferred during the latter part of gestation and whose rate of growth is high must soon exhaust the initial reserve of iron. At that time the already exist- [illegible] [illegible]mia of prematurity proper is [illegible] by the hypochromic anemia of iron deficiency. The full term infant whose mother suffered from iron deficiency during pregnancy has a normal hemoglobin level at birth but inadequate stores of iron and is prone to the development of an iron deficiency anemia which is preventable.[11]

The size of the reserve of iron may be materially reduced if early ligation of the cord deprives the newborn of the iron contained in the placental blood and normally converted to storage iron.[12] Such infants are more prone to the development of anemia than if this blood had been allowed to return to the circulation. Depletion of storage iron through chronic loss of blood is an infrequent occurrence in infancy but must be considered in regions where hookworm infection is prevalent. Because of the normal drain on the reserves of iron in infants, even acute loss of blood may be followed by a lasting anemia.

In the full term infant the iron stores available after birth are ordinarily sufficient to allow for the growth of the total hemoglobin mass until they can be replenished by iron from the diet. If food rich in iron is not then made available, anemia will develop on a nutritional basis alone. However, a deficiency anemia due to lack of iron is not necessarily the result of inadequate dietary intake; in fact, purely nutritional anemia is relatively infrequent even in infancy. In most instances infection is a precipitating factor.[13] It may interfere with ingestion or absorption of food iron by producing anorexia, vomiting or diarrhea, but its effect on the utilization of iron is far more direct and profound. Available evidence indicates [14] that in the presence of infection, iron is diverted from the marrow and immobilized in the tissues; hence it is not available for the synthesis of hemoglobin. This is true even for iron administered therapeutically. The infant is dependent on storage iron to a far greater extent than is the adult and thus is more liable to anemia when the marrow is cut off from its supply of iron. It is likely, however, that some infections at least have a still more immediate effect on erythropoiesis and can depress cellular regeneration directly.

Iron therapy is usually ineffective in the presence of continued infection but will nearly always produce remission once the infection is overcome. Whether a deficiency of copper is of clinical significance in human anemias is a question of little importance, because traces of copper are present in ordinary commercial iron preparations.

In Mediterranean anemia the red cells are deficient in hemoglobin; yet this hypochromic anemia is permanently resistant to iron therapy, apparently because iron cannot be utilized. The nature of this disease is not yet fully understood, but the known facts support the theory that the marrow cells are in some way unable to synthesize hemoglobin properly or at least in adequate amounts. The disease is hereditary and at present can best be explained as an inborn error of metabolism which affects the marrow cells.

In contrast to the megaloblastic and the hypochromic anemias, in which qualitative as well as quantitative changes in marrow function are evident, certain anemias are characterized by a simple quantitative reduction in the regeneration of erythroid cells which persists in spite of the increased demand caused by the anemia. These conditions may be designated as hypoplastic and aplastic states. The failure to make new erythrocytes produces a proportionate fall in hemoglobin and in the red blood cell count, and reticulocytosis and other signs of hematic regeneration are lacking. Similar blood pictures, however, are observed in the presence of actual hyperplasia of marrow with the arrest of maturation, when primitive cells are formed but are not released into the circulation.[15] The so-called hypoplastic and aplastic blood pictures can therefore reflect diametrically opposite conditions of the marrow and can be interpreted properly only through a study of the marrow. Therefore the concept of hypoplastic-aplastic states must be based on the process in the marrow rather than on observations in the blood.

Hypoplasia of the bone marrow may involve erythroid elements selectively or may affect all marrow cells. Erythroid cellular hypoplasia is found in anemias associated with a variety of conditions, such as infection, chronic renal disease and malignancy, and will persist until the underlying disease is eradicated.[16] Selective hypoplasia of erythroid marrow cells of completely obscure cause is seen in a rare chronic anemia of children, which appears to be congenital and which bears the name chronic hypoplastic anemia.[17] The production of leukocytes and platelets remains adequate, and the patients can live comfortably as long as transfusions at appropriate intervals provide the necessary red blood cells.

Occupation of the marrow space by such processes as fibrosis, sclerosis, osteopetrosis, metastases and infiltration with Gaucher's cells leads to a different picture. Such marrow as remains is highly active; the blood contains immature cells probably derived from extramedullary sites of blood formation, and the observations in this so-called myelophthisic anemia may simulate those of leukemia. Perhaps the anemia of leukemia is itself such a myelophthisic process;[16] in any event the leukemic cells proliferate at the expense of erythroid elements, and erythropoiesis is often reduced to the vanishing point.

Acc-No- 60

The term aplastic anemia is customarily reserved for states in which general depression of marrow activity causes leukopenia and thrombopenia as well as anemia. Such cases are extremely infrequent in childhood, and most of the anemias so classified eventually turn out to be leukemias of the so-called aleukemic type.

EXCESSIVE LOSS OF HEMOGLOBIN FROM THE CIRCULATION

In regard to the mechanisms of blood destruction, both physiologic and pathologic, many details remain to be clarified. The anemias characterized chiefly by increased destruction of blood are referred to by the generic term hemolytic anemias. Actually hemolysis in the sense of lysis of the erythrocytic membrane is only one of several mechanisms that may cause destruction of erythrocytes.[18] In the physiologic turnover hemolysis seems to play no part. The consensus is that during their stay in the circulation the erythrocytes are gradually fragmented by the constant of slight mechanical trauma to which they are exposed.[19] The minute remnants are eventually removed by phagocytosis in the reticuloendothelial system, mainly in the spleen. Phagocytosis of whole cells also occurs but is of minor importance, at least under normal conditions.[19]

The rate of destruction of the red blood cells in the absence of disease seems rather constant. I know of no compensatory mechanism whereby it could be decreased. An increase which might be called physiologic occurs in the first few days of life and accounts at least in part for the rapid reduction of the high hemoglobin levels of the newborn.[20] The details of this destructive process remain obscure.

The breakdown of hemoglobin results in the formation of bilirubin and its oxidation product, urobilinogen. With increased blood destruction the plasma bilirubin level tends to rise; but unless the hemolytic process is severe or hepatic function is impaired, excretion of the pigment by the liver prevents the rise to icteric levels, and clinical icterus is thus only a crude measure. Under certain assumptions the total excretion of urobilinogen in stools and urine is a much more delicate measure of the rate of destruction of blood than is the plasma bilirubin level. The total urobilinogen value depends, of course, on the total hemoglobin mass as well as on the turnover and is therefore much smaller in infants than in adults.

Free hemoglobin appears in plasma and urine only if there is hemolysis in the strict sense of the word and then only in the most fulminating conditions. This suggests that in most states associated with increased hematic destruction cellular mechanisms are involved.

Theoretically increased destruction of blood may be due to: (1) increased fragmentation of cells in the circulation; (2) structural anomalies of the red cells, which make them subject to destruction by the reticuloendothelial system; (3) sensitization of red cells, which makes them susceptible to phagocytosis while they are still intact; (4) increased activity of the reticuloendothelial system, causing its cells to engulf normal erythrocytes; (5) direct lysis in the circulation by hemolysins, bacterial toxins and poisons, and (6) parasitic invasion of red corpuscles, as in malaria.

It is uncertain whether all these mechanisms occur and to what extent the various factors may combine in a given type of hemolytic anemia. In most hemolytic states the reticuloendothelial system, and particularly the spleen, seems to be concerned in one way or another, whether as a passive acceptor of already doomed erythrocytes or as the initiator of the destructive process.

Mere evidence of increased blood destruction does not necessarily indicate an essentially hemolytic anemia but may reflect formation of abnormally vulnerable erythrocytes by a poorly functioning marrow. Signs of increased destruction of blood are evident in pernicious anemia, yet this disease is no longer considered as a hemolytic anemia but as a marrow deficiency state. Fragmentation of abnormal red corpuscles in the circulation is thought to account for the increased blood destruction in Mediterranean anemia,[21] and this disease is usually classified with the hemolytic anemias. But there is reason to consider a metabolic disturbance in marrow function as its essential feature and the fragmentation of the erythrocytes as incidental.

Exaggerated blood destruction is undoubtedly the significant mechanism in congenital hemolytic icterus and sickle cell anemia. The two diseases have many features in common. Both are constitutional anomalies characterized by hereditary transmission, exaggerated destruction of blood in the reticuloendothelial system and an anomalous structure of the mature erythrocytes. In congenital hemolytic icterus the erythrocytes are round instead of biconcave and in some way more susceptible to destruction by the reticuloendothelial system, notably the spleen. This abnormality is congenital and hardly due to substances elaborated within the spleen, since it persists after splenectomy. The fault lies with the cells themselves rather than with an abnormally active organ of destruction, as shown by the observations that cells from normal donors transfused to patients with congenital hemolytic icterus survive whereas the patient's cells disappear rapidly from the circulation of healthy persons.[22] However, since the abnormal cells are destroyed mainly by the spleen, removal of the spleen greatly decreases the rate of blood destruction. In sickle cell anemia the property of the red blood cells to sickle does not in itself account for the destruction of blood, because persons without anemia may have the sickle cell trait. It is uncertain whether the difference is due to a more pronounced abnormality in erythrocytic structure, as suggested by the more decided and more rapid sickling tendency of the cells in the anemic patients, or to greater activity of the destructive mechanisms. Because of the equivocal results of splenectomy in sickle cell anemia such mechanisms are thought to be widely distributed in the body. It has been observed, however, that immediate if only temporary cessation of all evidence of hemolysis occurs after splenectomy in sickle cell anemia quite comparable to the effect of this operation in congenital hemolytic icterus.[23]

The so-called acquired hemolytic anemias, acute and chronic, are still obscure in their genesis. Hemolysins have been demonstrated in some cases[24] but not in others. Sensitization of the red corpuscles may play a part, as in cases in which the hemolytic anemia follows infection after a latent interval. Certain chemical agents may also produce hemolysis in this manner. The sulfonamide compounds, for example, have no hemolytic effect in the test tube in concentrations comparable to those attained in the blood by therapeutic doses and do not cause hemolysis in normal persons. The infrequent instances of hemolytic anemia after sulfonamide therapy may therefore be related to sensitization of the erythrocytes or of the reticuloendothelial system or of both. In the acquired hemolytic anemias the spleen may not be primarily overactive but may act merely as an acceptor of altered erythrocytes, which might otherwise survive. Reduction of the destructive potential of the reticuloendothelial system by splenectomy may therefore be beneficial and at times lifesaving, but its effects are less predictable in acquired than in congenital hemolytic anemia.

Isoimmune bodies affecting the erythrocytes in the circulation are responsible for the acute hemolysis which follows the transfusion of mismatched blood. The A or B agglutinins are usually the effective agents, but antibodies of the Rh type may cause similar reactions.[25] The role of maternal anti-Rh substances in producing the hemolytic anemia of erythroblastosis in the infant is now firmly established,[26] whereas proof that anti-A or anti-B agglutinins of the mother can produce anemia in the offspring is less convincing.

It is not generally appreciated that there is a fundamental difference in the mechanisms of transfusion reactions and erythroblastosis. In transfusion reaction the donor cells are affected by the recipient's antibodies, while in erythroblastosis the patient's own cells are exposed to the effects of immune bodies. It is likely that the effect of the anti-Rh substances is not limited to the red corpuscles but affects other tissues as well and that this accounts for many of the manifestations of erythroblastosis which cannot be explained by hemolysis alone.

Bacterial toxins, apart from a possible effect on the bone marrow, may have a hemolytic action in the test tube and apparently also in the body. This is especially true for infections due to hemolytic streptococcus and Clostridium welchii. Recent studies seem to indicate, however, that in most of the anemias associated with infections the role of hemolysis is negligible compared to the effect on the production of red blood cells.[14a] The anemia which follows extensive burns is apt to be hemolytic in character and is thought to be due to endogenous poisons, perhaps protein cleavage products which in some way sensitize or destroy red blood cells.

This discussion is not intended to present a complete review of the pathogenesis of all types of anemia. The purpose of this presentation was to furnish basic concepts on which the practical management of anemia can be oriented.

CLASSIFICATION OF ANEMIA IN INFANTS AND CHILDREN

JAMES MARVIN BATY, M.D.
Boston

A complete classification of anemia as it is encountered in all age groups must include morphologic, etiologic and clinical considerations. For the purposes of a symposium such as is being conducted today it seems important to simplify the subject as far as possible so that the discussion may be of value to the practicing physician. For this reason a classification is presented in which the causes of anemia are arranged in the order of their occurrence in a group of hospital patients. This grouping is slightly different from the order in which Dr. Zuelzer has discussed the "Pathogenesis of Anemia." Although it is incomplete, almost all cases of anemia may be placed in one of its categories.

Analysis of 1,500 consecutive admissions to the Boston Floating Hospital was made to determine the incidence of anemia in hospital practice. It was found that 514 patients, or 34 per cent, showed a definite anemia with an erythrocyte count of less than 4,000,000 per cubic millimeter or a hemoglobin percentage below 70. It should be pointed out that the Boston Floating Hospital is largely charitable and that most of the patients are unable to pay the costs of medical care. The hygienic and dietary background of such a group of children is not comparable to that of patients under the care of private physicians. Furthermore, only those patients with severe anemia and those with unusual conditions received the careful consideration of the hematologist.

TABLE 1.—*Incidence of Anemia in 1,500 Patients Admitted to Boston Floating Hospital*

Age, Years	Number of Patients	Per Cent Anemic
0 to ½	237	38
½ to 1	178	47
1 to 2	240	51
2 to 5	285	34
5 to 12	560	22
Total	1,500	34

The incidence of anemia in these 1,500 patients is shown in table 1. The second year of life is the period in which there is the greatest incidence of anemia, about 51 per cent. Approximately 45 per cent of the children under 2 years of age and 25 per cent of those between ages 2 and 12 were anemic. The etiologic factors responsible for the anemia in the 514 patients were determined as far as possible. The anemia was secondary to infection in about half of the cases (table 2). I am unable to present figures showing the bacterial agents or the locus of the infections involved in these cases. Other factors which have been discussed by Dr. Zuelzer seemed to be of greater importance in the occurrence and the severity of the anemia in the individual instances.

From the Department of Pediatrics of the Tufts College Medical School, the Boston Floating Hospital and the Children's Clinic of the Boston Dispensary.

Read in a symposium on "Anemia in Infancy and Childhood" before the Section on Pediatrics at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 5, 1946.

In 92 per cent of the 514 patients with anemia the diminution in the hemoglobin and erythrocyte values were the result of infection, dietary deficiency, prematurity or some combination of these three factors. In the remaining 8 per cent the anemia was associated with congenital and familial conditions, acquired hemolytic states, primary hematic diseases and the other less common causes of anemia.

Table 2.—*Etiologic Factors in 514 Cases of Anemia*

	Number of Cases	Per Cent
Infection	252	49
Deficient diet	69	13
Prematurity	11	2
Combinations of foregoing	139	29
Miscellaneous	43	8

The classification in table 3 is arranged on an etiologic basis, more or less in the order of frequency of the etiologic factors. This is not offered as an inelastic classification but as a practical working basis for use in diagnosis and treatment.

The anemia associated with infection may be of three general types dependent on the mechanisms concerned in its production: (1) hypoplastic or aplastic anemia (diminished production of erythrocytes, the so-called toxic suppression of the bone marrow); (2) hemolytic anemia (increased destruction of circulating erythrocytes), and (3) secondary thrombopenic purpura (diminished production or increased destruction of blood platelets). In individual instances there may be all combinations of these mechanisms with resulting differences in the clinical manifestations.

Dietary anemia is most commonly the result of iron deficiency during either the prenatal or postnatal period due to an inadequate supply of iron-containing foods in the diet or a failure in absorption or utilization of iron.

Table 3.—*Anemia in Infants and Children*

1. Anemia secondary to infection
2. Dietary anemia (nutritional or alimentary anemia)
   Iron deficiency during:
      (a) Prenatal period
      (b) Postnatal period
3. Physiologic anemia of prematurity
4. Congenital and familial anemias:
   (a) Congenital hemolytic jaundice
   (b) Sickle cell anemia
   (c) Mediterranean anemia
5. Erythroblastosis (acquired hemolytic states)
6. Primary diseases of the blood:
   (a) Aplastic anemia
   (b) Purpura
   (c) Hemophilia
   (d) Leukemia
   (e) Lymphoblastoma (Hodgkins disease, lymphoma, etc.)
7. Anemia secondary to hemorrhage
8. A. Anemia associated with chemical poisons, such as benzene, lead, acetanilid and sulfonamide compounds
   B. Anemia associated with parasitic infection
   C. Anemia associated with neoplasms

In most instances there is hypochromia and microcytosis, and this type of anemia is frequently classified as hypochromic microcytic anemia. However, there may be a deficiency of the erythrocyte-maturing factor found in the liver, resulting in a macrocytic type of anemia which resembles pernicious anemia in many respects and which responds to folic acid.

The anemia of prematurity is physiologic in nature and is simply in a more pronounced degree the anemia which occurs in all infants during the neonatal period. The anemia is in proportion to the degree of prematurity, is severest at the third month of life and tends to disappear by the seventh month. The most important implication of this condition is that it sets the stage for the development of a more serious type of anemia if the infant suffers infection or dietary deficiency.

The congenital anemias include those conditions in which there is a congenital anomaly of the blood-forming organs which results in the production of abnormal erythrocytes. Although there is evidence of increased hemolysis in most instances, the fundamental disorder is the faulty formation of cells. These diseases may be racial and familial as well as congenital.

The fifth division of this classification, erythroblastosis, could properly be labeled acquired hemolytic states. In this case it would include other rarer conditions in addition to the hemolytic anemia of the neonatal period, which is on the basis of incompatibility of the blood groups of the mother and the infant.

The primary hematic diseases, hemorrhage and other miscellaneous causes of anemia are rare in infancy and early childhood but must be considered as possible etiologic factors in cases of obscure origin.

TREATMENT OF ANEMIAS IN INFANCY AND CHILDHOOD

H. G. PONCHER, M.D.
Chicago

The treatment of anemia at any age period must inevitably be concerned with etiologic and pathogenetic factors. Rational therapy is possible only when such factors are properly evaluated. Dr. Zuelzer has discussed the basic mechanisms by which anemia is produced in infants and children. Dr. Smith has indicated methods by which these can be detected, and Dr. Baty has grouped the anemias according to their combined pathogenetic, etiologic and clinical characteristics.

The significant point established in the discussion is that the peculiarities of the anemias of infancy and childhood are not due to a fundamental difference in the pathogenic mechanisms but to anatomic, physiologic and clinical features of the infantile organism which condition the response to the various etiologic factors. Some of these features are more important at one age period than at another. Because of this fact therapeutic principles applicable to anemia in general must be related to the modifying influences of the age period and the periods of life in which they occur.

ANEMIA IN THE NEWBORN (BIRTH TO ONE MONTH OF AGE)

Anemia occurring in the neonatal period (birth to 1 month of age) may be due to several factors but is usually on the basis of loss of blood or increased hematic destruction. The symptom complex known as hemolytic anemia of the newborn, or erythroblastosis fetalis, is the most prevalent and is most effectively treated with Rh-negative blood, especially during the first two weeks of life. The amount and frequency of the transfusions should be determined by the patient's general condition and the degree of anemia.

Read in a symposium on "Anemia in Infancy and Childhood" before the Section on Pediatrics at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 5, 1946.

Generally, a level of 3 million red blood cells and a hemoglobin of 8 Gm. are the minimum values to be achieved, and 10 cc. of blood per pound of body weight is the usual amount given at one time. In cases in which Rh-negative donors are not available blood from Rh-positive donors may be used if the plasma is separated and the red cells are washed and resuspended in isotonic solution of sodium chloride. The transfusion of Rh-positive blood without this preparation has been advised by some, but jaundice is often intensified and recovery is slower than with Rh-negative blood. Diamond has shown that many of the baby's red blood cells are bound to the so-called blocking antibody and that these are capable of agglutinating two or three times as much additional Rh-positive blood. This phenomenon may be demonstrated by a slide test devised by Diamond.

In all patients with severe anemia at any age period requiring frequent transfusions of blood Rh typing should be done, because an Rh-negative recipient may develop a sufficient anti-Rh agglutinin titer to cause a hemolytic reaction when Rh-positive blood is frequently administered. While anti-Rh agglutinins already exist in the blood of the newborn through isoimmunization from the mother, Rh-negative blood should be given whenever possible, reports to the contrary notwithstanding.

Hemorrhage in the newborn period is most frequently accidental and is usually associated with slipped cord ligature and trauma, and the blood lost should be replaced by transfused blood. Stewart Clifford of Boston has expressed the opinion that asphyxial bleeding is of greater importance than either traumatic or accidental factors and that appropriate measures to reduce asphyxial states would decrease the incidence of hemorrhage in the newborn. Prophylactic administration of vitamin K to the mother and infant has practically eliminated the incidence of hemorrhagic disease of the newborn (hypoprothrombinemia neonatorum). Hemophilia is seldom encountered in the newborn period except through surgical intervention or routine circumcision and is also effectively treated by the transfusion of blood. Congenital thrombocytopenic purpura is infrequently seen at this age, and when it is, blood transfusion rather than splenectomy is the treatment of choice, unless the disease cannot be controlled by this procedure. Bleeding from ectopic islands of gastric tissue scattered through the intestinal tract may account for obscure prolonged gastrointestinal bleeding at this period, just as it does in a Meckel's diverticulum.

Infection in the newborn period is often associated with a bacteremia and acute hemolytic anemia or with bleeding and purpura due to platelet depression. Transfusion in addition to chemotherapy is therefore indicated. In my experience and that of others anemia in the newborn that can be attributed to infection is less common in recent years.

A poorly defined entity, which is known as chronic hypoplastic anemia, may occur in the latter part of the neonatal period. It is an anemia of the normocytic type and involves the production of red blood cells without significant changes in white blood cells and platelets. No known cause has been found for this condition. Marrow stimulants have been advocated, but to date blood transfusion is the only satisfactory method of treatment. Splenectomy has been tried in some cases, but the procedure has not had sufficient success to warrant its use as a routine method of treatment.

ANEMIA IN INFANTS (ONE MONTH TO TWO YEARS)

Anemia in infancy is predominantly due to iron deficiency, and the red blood cells become deficient in hemoglobin (hypochromic) and smaller (microcytic) than normal. The obvious primary therapeutic consideration is the correction of the deficiency state by the administration of iron to the infant. On a purely theoretic basis other materials needed for hemoglobin synthesis may be lacking (protein, pigments such as chlorophyl, copper and other trace elements). Inferences drawn from animal experimentation would support such a possibility. Such evidence, however, does not justify the numerous shotgun proprietary preparations that are constantly offered to the profession without clinical facts to support their use. Preparations of this type increase the cost of medical care and minimize the careful evaluation of the cause of the anemia which is so important to well conceived and intelligent treatment.

The clinical evidence for the use of copper in hypochromic microcytic anemias of infants and children is conflicting. It is apparent from experimental work that copper is needed as a catalyst for hemoglobin synthesis and that it is concerned with the utilization of iron. It has not been demonstrated clinically, however, that routine use of copper with iron is necessary or desirable because traces of copper are present in most iron preparations and in the diet. This does not mean that copper is not needed, it merely suggests that routine supplemental use of copper is unnecessary unless the infant has been fed on an exclusive milk diet. In anemia which has proved refractory to treatment with iron in the absence of infection and other conditions which interfere with a favorable therapeutic response to iron, copper deficiency may conceivably be present, and the addition of small amounts of copper (1 cc. per kilogram of body weight of a 0.5 per cent solution of copper sulfate) may be necessary for adequate treatment. This dose should be smaller in older children, and even in young infants smaller doses should be given at first. The indication for such therapy has been minimal in my experience.

The exact status of the whole liver or its water-soluble fraction (Whipple) in the treatment of microcytic hypochromic anemias of children has not been accurately determined. It is possible and reasonable to assume that other nutritional factors necessary for the synthesis of the hemoglobin molecule may at times be deficient and that the deficiency can be corrected by feeding whole liver or its water-soluble fraction. However, this does not call for routine use of expensive liver and iron combinations that are without indication. The indiscriminate use of vitamins in the treatment of iron deficiency anemia beyond that needed for normal nutritional balance is also ill conceived and without sound clinical or experimental evidence. Fifteen to 20 Gm. of puréed liver daily may be given to infants up to 2 years of age, and 30 to 40 Gm. daily to children from the ages of 2 to 6 years.

The therapeutic management of microcytic hypochromic anemia often consists in something more than the correction of a possible deficiency of some substance needed to synthesize the hemoglobin. Insufficient store of iron combined with increased demand due to a rapid rate of growth, as seen particularly in prematurely born infants, is an important mechanism in the production of iron deficiency. Factors which lead to deficient absorption or excessive loss or which inhibit the utilization of iron are of equal if not greater importance in private practice.

It has been brought out in the discussion that infection and dietary deficiency play a more prominent role in the production of anemias of infancy and childhood than any other factor. This is especially true if such factors are present in the first two years of life. Close to 90 per cent of the anemias seen in pediatric practice are due to infection or dietary deficiency alone or in combination. If vomiting or diarrhea are present, failure of absorption and utilization of materials necessary for the formation of blood are added complications. Deficient iron stores due to maternal anemia during gestation, premature ligation of the umbilical cord at birth and premature and multiple births, together with the factor of increased need for iron due to a rapidly expanding blood volume, hasten the onset of hypochromic anemia and accentuate its severity.

Prophylaxis and treatment of the iron deficiency state should therefore be concerned with something more than administration of a suitable preparation of iron or, failing in this therapeutic venture, recourse to the proprietary shotgun preparations. Attempts should always be made to discover all possible causes for the iron deficiency state. In the adult this is usually chronic loss of blood; in the infant it is more likely dietary deficiency in the presence of increased demand or insufficient reserve, disordered alimentation and infection and frequently two or more of the preceding causes.

Iron therapy has been a controversial subject since its inception. Time does not permit a review of the comprehensive work of Whipple, Heath, Hahn, Wintrobe, Moore and others who have made significant contributions in this field. Moore and his group have conclusively demonstrated that iron is absorbed from the gastrointestinal tract in the soluble or ionized ferrous state. The ionization is facilitated by gastric acid if iron is not too firmly linked with other compounds. The degree to which ferric salts are absorbed depends on the capacity of the gastrointestinal tract to reduce them to the ferrous form. For extemporaneous prescription writing, the use of ferrous salts in acid vehicles would therefore seem to be the most effective type of medication. The following prescription is an example:

Ferrous sulfate	9.0 cc.
Spirit of peppermint	1.0 cc.
Solution of amaranth	1.0 cc.
Syrup of citric acid	60.0 cc.
Simple syrup to make	120.0 cc.

Drams 1 (4 cc.) equals approximately 2.5 grains (0.16 Gm.) anhydrous ferrous sulfate

The use of reducing agents like ascorbic acid or citrus fruits given with iron salts may enhance absorption.

The controversy concerning the relative value of various preparations of iron can be settled practically by stating that since larger doses of ferric salts are necessary than with the ferrous form and since large doses of iron are irritating to the gastrointestinal tract, the practical expedient is to use the preparation less apt to upset the infant or child, other factors being equal. Organic preparations of iron in the ferrous form have been preferred by some for this reason. Ferrous gluconate is an example and is an acceptable preparation. The parenteral use of iron is seldom necessary and is a painful procedure. The amount of iron present in the preparation is no index of its efficacy. It is the amount of iron absorbed and utilized, not the actual iron present, that controls hemoglobin regeneration.

The dosage of iron for therapeutic purposes is subject to wide variations, but the following dosage of ferrous sulfate is effective and is recommended: Birth to 2 years, 4 to 6 grains (0.26 to 0.39 Gm.) daily; 2 to 6 years, 6 to 8 grains (0.39 to 0.52 Gm.) daily, and 6 to 12 years, 10 to 12 grains (0.65 to 0.78 Gm.) daily. Ferric and ammonium citrate is given in daily doses of 2 cc. per kilogram body weight (1 cc. per pound) of a 10 per cent solution. The initial dose of iron should be small, and optimal doses should be approached gradually. The effectiveness of the preparation or adequacy of the dose of iron may be checked by the reticulocyte count just as one does with liver extract or folic acid in pernicious anemia. Within about three days after iron therapy is begun the reticulocytes begin to rise and reach a peak in seven to ten days. The level of hemoglobin and the peak of reticulocytosis is usually in an inverse ratio. The lower the initial hemoglobin value the higher the reticulocyte response which one will obtain with adequate iron medication, and this holds true with the daily increase of hemoglobin in response to treatment. The rate of increase of hemoglobin in response to iron therapy definitely slows as normal values are approached. If a patient with hypochromic microcytic anemia fails to respond after receiving adequate doses of iron and shows no reticulocytic response or disordered alimentation, this is suggestive of infection, chronic inflammation or neoplastic disease. In the absence of these factors, copper, whole liver or its water-soluble fraction may be tried. Such cases are few in number if the patient is on a diet well balanced in protein, mineral-rich foods and vitamins.

Thus far only iron deficiency or microcytic hypochromic anemias have been mentioned, because they are the anemias most prevalent in infants. Dr. Zuelzer has brought out that deficiency states leading to anemia may be produced either because iron and other materials used in the synthesis of hemoglobin are not available to otherwise normal cells or because the cells themselves are abnormal due to deficiency in an essential factor. Pernicious anemia in adults is an example of the latter. True pernicious anemia is rare in children below the age of 12 years. Pernicious-anemia-like macrocytic states of the blood have been observed in infants and children from time to time, in patients with celiac disease, in those with hepatic disease, infection, congenital malformation of the intestine and nutritional deficiency (especially infants fed goat's milk exclusive of other foods). Dr. Zuelzer has recently reported a series of 25 infants with macrocytic anemia, which he proposes tentatively to call megaloblastic anemia. Leukopenia with degenerative changes in the granulocytes and thrombopenia were also present. The syndrome may be produced by a variety of causative agents but always by the same basic mechanism, which is manifested by a characteristic megaloblastic bone marrow. The patients ranged from 2 to 16 months of age, and most of them had infections of the upper part of the respiratory tract or a nutritional disturbance and deficiency. Therapy with folic acid or liver extract was effective and dramatic with a characteristic reticulocytic response. The megaloblastic pattern in the bone marrow was transformed to normal within a few days. In contrast with pernicious anemia, the deficiency is not on a constitutional basis and once the deficiency is successfully treated relapses do not occur. The oral dose of synthetic folic acid is 5 to 20 mg. daily, the intramuscular 1 to 2 mg., depending on the severity of the case. Where parenteral liver extract is used intramuscularly ½ to 2 units daily of the crude extract is advised, depending on the severity of the case and the reticulocytic response.

Another factor apparently essential to erythropoiesis is vitamin C, or ascorbic acid. Anemia of this type shows its greatest incidence at this age period. Whereas uncomplicated iron deficiencies are microcytic and hypochromic and folic acid deficiencies are usually macrocytic and hyperchromic, anemia associated with uncomplicated scurvy is usually normocytic and normochromic. When complicated by hemorrhage and infection it may reveal iron deficiency, and when it is associated with deficiency in folic acid and other nutritional factors it may be macrocytic in type. The bone marrow pattern in uncomplicated scurvy is normoblastic in type and is not transformed by liver, folic acid or iron unless complicated by factors mentioned previously. Specific therapy with citrus fruit juices or ascorbic acid is necessary for cure and is accompanied by a prompt reticulocytosis. In cases in which iron deficiency or folic acid deficiency accompanies scurvy some response is obtained to treatment with iron or folic acid, but it does not specifically cure the primary cause of the anemia. Some observers feel that the role of ascorbic acid in the production of anemia as a primary mechanism is inconclusive.

ANEMIA IN PRE-SCHOOL CHILDREN (TWO TO SIX YEARS OF AGE)

Anemia occurring during the age period 2 to 6 years is usually due to nutritional deficiency and infection. Infection is a dominant factor and according to Dr. Louis Diamond's figures from Boston Children's Hospital produces anemia in the following roughly estimated groupings: 60 per cent are due to interference by infection with elements necessary for blood building; 30 per cent are due to decreased production of erythrocytes; 9 per cent are due to increased destruction of red cells, and 1 per cent are due to interference with platelet production and a bleeding state.

Anemia on the basis of infection may be of mixed type with microcytosis and macrocytosis at this age period. Such patients respond best to iron and liver therapy after the cause has been removed.

Congenital anemias may have their inception earlier but usually manifest themselves in greatest numbers at this age period. Mediterranean anemia, or Cooley's anemia, is resistant to iron therapy and other forms of treatment, although it is hypochromic in type. The exact nature of this disease is poorly understood, but the best explanation is that it is due to an inborn error of metabolism wherein the marrow cells are unable to utilize iron. Splenectomy has been advised, but it is of little permanent value. The same statement would hold true for the therapy of sickle cell anemia. Congenital hemolytic icterus responds as effectively to splenectomy in this age group as it does in adults.

Because of the predominance of infection at this age period, cases of acute hemolytic anemia or marrow depression due to drugs, particularly the sulfonamide group, are not uncommon, and acquired hemolytic states due to infection, drugs and transfusion reactions occur with increased frequency. An acute form of hemolytic anemia known as Lederer's anemia is difficult to classify on any confirmed etiologic basis but is most effectively treated with blood transfusions. Mention has already been made of the desirability of typing any patient requiring frequent blood transfusion for the Rh factor, since Rh-negative recipients may acquire a sufficient titer of positive Rh agglutinins with repeated injections of Rh-positive blood to have severe hemolytic reactions.

ANEMIA IN SCHOOL CHILDREN (SIX TO TWELVE YEARS OF AGE)

Anemia during the school age period is predominantly due to chronic infection, chronic inflammatory disease or loss of blood. Streptococcic infections and their complications head the list. Pyogenic infection, chronic sinusitis, pneumonia, nephritis, rheumatic fever, tuberculosis and symptomatic purpura are prominent as causes. Under normal conditions the iron reserves are fairly well stabilized at this age and iron deficiency is less common. Effective treatment of the cause of the anemia, together with the institution of a balanced diet, is effective unless the anemia is severe and requires blood transfusions as a palliative measure until the cause can be removed. The constant loss of blood due to the menstrual cycle in girls at puberty together with the growth spurt occurring at that period are basic to the iron deficiency state seen at this time. In the presence of a poorly balanced diet, particularly of iron-containing foods, the degree of anemia may become pronounced. Iron prophylaxis and therapy is important in the management of such cases.

SUMMARY AND CONCLUSIONS

Rational therapy demands a thorough understanding of the physiologic and pathologic factors of the age period in which anemia develops. While deficiency of nutritional substances necessary for the synthesis of hemoglobin and for normal erythropoiesis are important, factors which increase the demand, cause excessive loss or interfere with absorption and utilization of these substances are especially important causes for anemia during the active period of growth. It is for this reason that treatment of anemia in infants and children must be approached from a broad clinical perspective as well as from the point of view of the specific disciplines of hematology.

1819 West Polk Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. SMITH, ZUELZER, BATY AND PONCHER

Dr. M. M. Wintrobe, Salt Lake City: What Dr. Baty had to say concerning the frequency of the various types of anemia emphasizes a significant point. While there has been a great deal of progress in hematology in the past two decades the advancement has been made in the understanding of the less common conditions and the more dramatic ones. Much less has been learned about the most commonly observed type of anemia, that which is associated with infection. In the study of the pathogenesis of such anemia it has been learned that in the presence of infection the plasma iron content is consistently and strikingly low. At the same time, the serum copper is elevated and the amount of free protoporphyrin in the erythrocytes is greater than normal. Pursuing these observations further, it was found that when iron was given by mouth, the plasma iron in patients with infection did not rise at all. However, this flat plasma iron curve is not due to a failure of absorption of iron, for if one gives such persons iron intravenously, one finds that the plasma iron content, unlike that in normal subjects, falls extremely rapidly. It has been possible to show that in the presence of infection there exists some disturbance which leads to the rapid withdrawal of iron from the plasma. If such persons are given radioactive iron the iron is incorporated in the red cells to a much smaller extent than occurs in normal persons. By tracing the distribution of the radioactive iron in the various tissues, it has been found that the greatest proportion is located in the liver. While it is true, as Menkin has reported, that a greater quantity of iron is found in inflamed tissue than in the corresponding normal tissue, the quantity of iron going to inflamed tissue cannot account for the severe drain on iron which occurs in the presence of infection. Investigators are seeking to learn the nature and cause of this disturbance in the metabolism of iron. With regard to the diagnosis of anemia, I would like to make a plea to the physician to acquire the habit of looking at the blood smear of his patient himself. While he will never leave to an assistant the final examination of the heart or some other part of the physical examination, it is strange how even the most painstaking physicians are ready to leave the examination of the blood smear to a technician. Prophylaxis is extremely important in the management of hemolytic disease of the newborn. A life may be saved if one is prepared by having been forewarned through having taken a satisfactory history from the prospective mother and having made subsequent appropriate examinations and preparations. If suitable blood for transfusion is available sufficiently soon, the child's life may be saved. In connection with the pathogenesis of hemolytic disease of the newborn the point may be made again that one must avoid giving blood transfusions indiscriminately and thus running the risk of building up anti-Rh or other agglutinins.

Dr. Carl V. Moore, St. Louis: I should like to add my tribute to that of Dr. Wintrobe to the four men who participated in this symposium. The task of reviewing so broad a subject in the time available was well performed. Dr. Zuelzer correctly emphasized the importance of oxygen tension as a regulator of the rate of red blood cell formation. It is well known that the lowered oxygen tension of high altitudes stimulates erythrocytogenesis. Several years ago it was possible to demonstrate that the reverse is also true: high oxygen tensions depress the red-blood-cell-forming elements in bone marrow. Patients with sickle cell anemia were given high concentrations of oxygen by face mask continuously for twelve days. Regularly, on about the sixth day of oxygen administration, the initially elevated reticulocyte levels began to fall to normal values. Shortly thereafter the red blood cell count also began to decrease; on several occasions, it was a million cells lower by the end of the period than it had been before the administration of oxygen was started. After the mask was removed on the twelfth day, there was a great outpouring of reticulocytes and a subsequent rise in the erythrocyte values. What Dr. Poncher has said about keeping iron therapy pure is extremely appropriate. There is no evidence to indicate that the addition of thiamine, riboflavin or any other vitamin to iron makes the iron more effective therapeutically unless a specific vitamin deficiency coexists. These combinations probably have been developed because physicians are dissatisfied with the effect of iron in the treatment of anemias. Iron is of value, however, only when a patient is deficient in iron; that is, when a hypochromic anemia is present. Under these circumstances it will work by itself. In the other forms of anemia iron deficiency is not a primary factor in pathogenesis and cannot be expected to be corrective, with or without copper and the various vitamins. Diagnosis and appreciation of etiologic factors can be sharpened considerably if use of the shot-gun iron preparations is avoided.

ALLERGIC PERITONITIS

Report of a Case

AGERICO B. M. SISON, M.D.

JOSE A. SILVA, M.D.
and
POTENCIANA C. CHAVEZ, M.D.
Manila, P. I.

Several forms of allergy have been reported in the literature.[1] Among the commoner ones are hay fever, eczema, angioneurotic edema, gastrointestinal allergy, allergic migraine, serum sickness, urogenital allergy, nervous allergy, toxic allergy, drug allergy, allergic headache, bronchial asthma, ophthalmic migraine, some forms of dermatoses and periarteritis nodosa of allergic nature or in association with some other manifestations of allergy.[2] A careful search of our available literature on allergy has not revealed a reported case of allergic peritonitis. Although Harkavy[3] has reported 2 cases of "eosinophilic peritonitis," which our case closely resembles, yet there were present associated involvement of other organs in his cases. In the case here reported the involvement is purely peritoneal. The features, clinical signs and symptoms, laboratory observations and therapeutic responses are so distinctive of allergy that we venture to label this case as allergic peritonitis. Our fortunate discovery of this case may henceforth call attention to one form of allergy which has not been reported heretofore.

REPORT OF CASE

Mrs. V. J. L., aged 31, a married Filipino piano teacher, was admitted for the fifth time to the Philippine General Hospital, with a repetition of the attacks she had had previously.

Previous History.—First Illness: The first attack occurred four years ago, when some two weeks after her first delivery on Jan. 13, 1942 she suddenly experienced severe epigastric pain radiating over the whole abdomen and accompanied with nausea and vomiting, abdominal tenderness and rigidity. The pain was extremely severe; it made her double up, and it occurred in paroxysms at intervals of a few minutes. Blood examination revealed a leukocytosis of 20,000 with predominance of polymorphonuclears and eosinophils (15 per cent). She was, however, only slightly febrile (37.5 C., 99.5 F.). Because of the acute abdominal pain, the tenderness and rigidity over the abdomen (especially noticeable in the right lower quadrant) and the leukocytosis her illness was diagnosed as acute appendicitis, and she was operated on. To the surgeon's surprise, the appendix was normal. It was nevertheless removed. The most noteworthy observation, however, was the presence in the abdominal cavity of an undue amount of amber-colored, slightly turbid fluid, of which 1 liter was removed.

Second Admission: The wound healed normally, but the epigastric pain, nausea and vomiting persisted, increasing in intensity and frequency as the days passed. Associated with

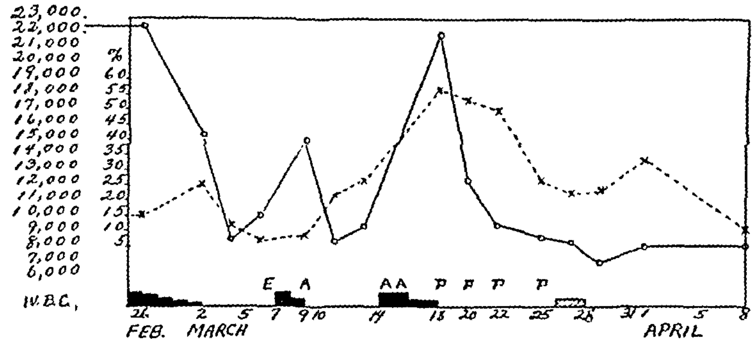
these symptoms the patient noted a gradual increase in the size of her abdomen sufficient to cause some respiratory embarrassment. After three weeks she had to be readmitted. On this admission blood examination revealed a leukocytosis of 30,000 with 38 per cent eosinophils. A laparotomy was performed and some 3 liters of abdominal fluid was removed. Careful search did not reveal anything abnormal to account for the presence of fluid. Section of the peritoneum revealed no histologic abnormality save for congestion. Examination of the ascitic fluid revealed that it was in the nature of an exudate with high cellular count, high albumin percentage, high specific gravity and high eosinophilic count (38 per cent). Examination of the peripheral blood subsequently revealed a gradual lowering of the leukocyte and eosinophile counts during the next two months until the figures became normal. The laparotomy wound healed uneventfully and the symptoms of pain, nausea and vomiting subsided with the disappearance of the ascites. The disappearance of the clinical signs and symptoms coincided with the gradual return to normalcy of the leukocyte and differential counts. On account of the high eosinophilia, several stool examinations were done for intestinal parasites, but they were consistently negative.

Subsequent Course: On discharge the patient enjoyed comparatively good health and had no complaints whatsoever until after her second delivery in October 1943. The symptoms and signs, which were identical to those of her previous admissions, although less intense, were felt one month after her delivery. In view of our previous experience with her condition she was treated conservatively with sedatives for the pain and regular injections of dextrose and calcium. With this treatment alone she improved. Examinations of blood and of ascitic fluid revealed essentially the same picture as before, and their gradual return to normal kept pace with the clinical improvement. She went home improved and enjoyed good health until July 1944, at which time she was stricken with typhoid fever.



Correlation of hematologic data with abdominal pain and therapy. The unbroken line represents the total white blood cell count; the broken line, the eosinophil percentage; filled in area, abdominal pains; diagonally lined area, menses; A, epinephrine injections; E, estrone, and P, progesterone injections.

Present Illness.—History: In October 1945, which was the sixth month of her third pregnancy, she experienced the same symptoms as on her previous admissions. However, the symptoms were felt during and not after pregnancy, as they had been before. The symptoms were comparatively much less in intensity, and the abdominal enlargement seemed only commensurate with the stage of pregnancy. Examination of the blood revealed the same features as before though less in degree. No paracentesis abdominis was done this time. She improved on conservative management within a week.

Her present admission, which is her fifth, followed her last delivery on Jan. 31, 1946 by twenty-six days. The symptoms were first ushered in by epigastric fulness followed by severe pains which radiated downward towards the umbilicus. The pains were severe, paroxysmal and came at intervals of some three to five minutes. They were exacerbated by movements of the body and accompanied by nausea, vomiting of the ingested food and some respiratory distress. The symptoms increased in severity as days passed. Her husband, who is a physician, gave her intravenous injections of dextrose and calcium gluconate, but little relief was obtained. Twice she had to be given morphine for the pain. Gradually, it was also noted by the patient that her abdomen was increasing in size and that the sensation of fulness and bloating was becoming more pronounced. These symptoms did not abate, so she again sought admission. Just before entry, however, she had an extremely acute attack of pain that required morphine to quiet her.

As will be noted all the attacks followed a uniform clinical and laboratory pattern. No jaundice, melena, hematemesis or diarrhea was observed during any of these admissions.

Her condition on admission on February 26 was that of a slightly febrile (37.8 C., 100.04 F.) pale patient under the influence of morphine. She was slightly drowsy and answered questions sluggishly. She still complained of pain, though it was dulled by morphine. Appetite was absent, the bowels constipated, the pulse rate 86, the respiratory rate 20 and the blood pressure 120 systolic and 68 diastolic.

Physical Examination: Physical examination revealed essentially normal conditions except in the abdomen. The abdominal wall was slightly tense and hyperpigmented, with striae of pregnancy. Two scars, that of the appendectomy and that of the laparotomy, were visible. There was evident sagging on both sides. On palpation there was generalized moderate tenderness and rigidity, apparently increased in the right upper quadrant of the abdomen. There were unmistakable signs of ascites.

Previous Diseases: From childhood up to the age of 17 the patient had recurrent attacks of urticaria apparently brought about by the ingestion of sea foods. At the age of 19 she had an attack of moderate epigastric pain and vomiting which was diagnosed as acute gastritis. Examination of the blood done then revealed normal findings. At 21 years of age moderate pallor developed, and she had frequent attacks of dizziness which were diagnosed as due to secondary anemia. She took the contents of a bottle of pills of ferrous carbonate, which relieved her symptoms completely. In December 1939 she had rheumatic polyarthritis which responded to salicylate treatment and extraction of an abscessed tooth. Examination of the blood at this time revealed a white cell count of 12,000 with no eosinophilia. The patient had typhoid fever in July 1944, as stated previously.

Family History: A brother had a history of repeated urticarial attacks. Her father used to suffer from bronchial asthma. Her mother and sister had rheumatic polyarthritis. The results of leukocyte, differential and stool examinations done to these members of her family revealed normal conditions. However, these tests were performed when they were symptom-free.

Laboratory Examinations: Results of examinations of the blood are given in the hematologic studies and on the accompanying chart. Urinalyses were normal on several occasions. The feces were consistently negative for intestinal parasites. Bilirubin tests 1 and 2 and the Takata-Ara test were within normal limits. The cholesterol level was 166 mg. per hundred cubic centimeters. Blood smears for malaria were negative.

The ascitic fluid was light yellow, turbid, rather viscid and slimy. The total cell count was 5,040 with a differential of polymorphonuclears 63 per cent; lymphocytes 7 per cent; mesothelials 1 per cent; endothelials 5 per cent; eosinophils 12 per cent; basophils 2 per cent, and macrocytes, 10 per cent. Guinea pig inoculation of the ascitic fluid was negative, and culture of ascitic fluid was sterile. The sedimentation rate of the blood was normal.

Hematologic Studies: As will be seen in the chart, the white blood cell count ranged from 8,400 to 22,500, the highest count coinciding with the extremely severe pains on admission. During the attacks of pain there was a corresponding rise in the total white cell count.

The eosinophils ranged from 5.5 to 57 per cent. Unlike the behavior of the total cell counts, the increase in the percentage of eosinophils did not correspond with the attacks of pains. However, the eosinophils were observed to present atypical variations during the attacks of pains, as follows: First, the eosinophils were found hard to stain with Wright's, i. e., the granules did not have the crimson red and purple nuclei as seen in the normal smear. The cell seemed larger than the polymorphonuclear leukocytes when viewed side by side at the center of the smear. There were few vacuolations scattered irregularly around the periphery. The granules were pale pink, more numerous between the lobes of the nucleus and especially affecting those eosinophils with two nuclear lobes. All along the periphery there were scanty granulations, and between the center of the cell and the periphery the granules could almost be counted if there were facilities to do so. The cytoplasm was finely bluish and especially noticeable when there were no granulations.

This atypical appearance of the eosinophils gradually reverted to normal as the clinical signs and symptoms improved, only to be noted again with the return of abdominal pains. The same atypical appearance of the eosinophils was also observed in the ascitic fluid.

Course in the Ward: From admission on Feb. 26, 1946 to March 2, the patient had a low grade fever not above 38 C. (100.4 F.), with associated abdominal pains. Dextrose and calcium were given on alternate days. The pains were not felt from March 3 to 7. Estrone, 1,000 units, was injected at 10 a. m. of March 7, then at 5 a. m. March 8, very severe abdominal pains simulating those felt on admission were observed. Pains were felt subsequently on March 9, 14, 15, 16 and 17. Progesterone was subsequently given, after which no pains were felt. (See chart for better comprehension.)

COMMENT

Salient Features.—The salient features in this case are: (1) the presence of allergy and rheumatic diathesis in some members of the family, (2) the history of repeated attacks of urticaria in the patient, (3) the association of the symptoms with pregnancy and the puerperium (one attack occurred at the sixth month of her second pregnancy and 3 attacks occurred from two to four weeks postpartum), (4) the leukocytosis with eosinophilia during attacks, (5) the syndrome of acute pain in the abdomen during attacks, (6) evidences of ascites during attacks, (7) the intervals of comparative good health, (8) the exudative and eosinophilic character of the ascitic fluid and (9) the apparent absence of a septic focus in the abdominal cavity which could explain the preceding symptoms.

Differential Diagnosis.—In the differential diagnosis we had for consideration the following diseases:

1. Portal cirrhosis was ruled out by normal hepatic function, absence of splenomegaly, the periodicity of symptoms, the absence of evidences of collateral circulation, the exudative and eosinophilic nature of the ascitic fluid and the symptoms of acute abdominal distress.

2. Chronic nephritis was ruled out by the absence of symptoms referable to the urinary tract, normal urinalyses, normal blood pressure, the nature of the ascitic fluid, the periodicity of attacks and the exudative nature of the ascitic fluid.

3. Tuberculous peritonitis was ruled out by the absence of a pulmonary focus, the periodicity of the attacks, the eosinophilic nature of the ascitic fluid, the relative good health of the patient during the intervals and the negative result of guinea pig inoculation with the ascitic fluid.

4. Intestinal parasitism was considered on account of the eosinophilia, but the stool cultures have been consistently negative.

5. Trichinosis was considered because of the decided eosinophilia. Up to the present time no case of trichinosis in a Filipino has ever been reported. Even among the swine no case has yet been discovered by government veterinarians. Clinically, trichinosis can be ruled out by the absence of history of ingestion of raw pork, the absence of symptoms indicative of skeletal involvement, the periodicity of attacks and signs of ascites, which is not found in trichinosis.

6. Periarteritis nodosa [4] was most difficult to exclude, especially if we kept in mind that some cases of periarteritis nodosa are of allergic origin. The acute abdominal symptoms, eosinophilia in the blood and in the ascitic fluid were points in favor of a diagnosis of periarteritis nodosa. Against these were: the periodicity of symptoms; spontaneous remissions; association with pregnancy and the puerperium; absence of involvement of other organs, such as the liver, heart, spleen, kidneys and brain, and absence of evidences of thrombosis, infarction or aneurysm of the mesenteric vessels on laparotomy.

In this regard the report of Harkavy [3] may be mentioned. He described 2 patients with a syndrome of what he termed "eosinophilic peritonitis." These 2 patients (cases 6 and 7) presented, aside from the peritonitis, involvement of other organs such as the liver, lungs and heart, giving a picture of polyserositis of the nature of periarteritis nodosa. In the case herein reported there were no evidences of involvement of any other organ, save for a previous history of urticaria which, however, was apparently independent of the presenting signs and symptoms.

Mechanism of the Ascites.—The possible mechanism of the ascites could not be determined definitely, but we offer the following analysis.

The liver may first be considered. Ascites of hepatic origin may be produced by (*a*) passive congestion, (*b*) portal obstruction or (*c*) periarteritis nodosa with hepatic localization.

Passive congestion was ruled out by the absence of hepatomegaly, cardiac disease, hypoproteinemia or any other condition that may give rise to chronic passive congestion. The exudative and eosinophilic nature of the ascitic fluid, the periodicity and the presence of severe pains were all against this possibility.

Portal obstruction may either be thrombosis or phlebitis. This was ruled out by the absence of splenomegaly, collateral circulation, periodicity of the attacks and the exudative and eosinophilic nature of the ascitic fluid.

The liver as the seat of periarteritis nodosa has been reported.[5] While this possibility may be entertained, yet the periodicity of the attacks, the normal hepatic function, the spontaneous remissions, the association with pregnancy and the puerperium were against such a possibility.

By exclusion, the only logical thing to suspect was the peritoneum, that is, a peritonitis which was proved aseptic by culture and inoculation.

The Allergen.—We are not in a position to define the possible allergen in this case. One outstanding fact, however, is that the symptoms were always associated with pregnancy and the puerperium. Once the symptoms were felt at the *sixth month of the third* pregnancy and thrice they were felt two to four weeks after delivery. These observations seem to suggest the possible role of the gonadotropic and/or sex hormones in the etiology of the allergy. On account of our lack of facilities to determine blood or urinary gonadotropic or sex hormones, however, we were not in a position to define specifically the role of said hormones in the phenomena observed. In an attempt to ascertain the role of the sex hormones in the etiology of the case we undertook some simple procedures guided only by clinical observations, which fall short in scientific accuracy in such investigations as these.

After a few days, when the patient no longer felt the pain and was resting comfortably, an injection of estrone was given. The resident physician in charge was instructed to administer intradermally 0.1 cc. of the *2,000 unit strength of estrone. Through inadvertence* 1 cc. of the medicament was given subcutaneously into the right forearm. After eighteen hours there developed a reaction to the injection, and it consisted of severe abdominal pains similar in character and degree to the pains which the patient had felt on admission. These pains, however, responded dramatically to an injection of 0.5 cc. of a 1 : 1,000 solution of epinephrine. She again had pains of a similar nature on the second, fifth, sixth, seventh and eighth day after receiving the injections of estrone. These pains were alleviated promptly by injections of epinephrine. On the ninth day, we began to give her injections of progesterone every other day for five injections, and since then the abdominal pains have never recurred. Also there was observed a gradual decrease in the size of her abdomen. For purposes of provocation, another injection of 2,000 units of estrone was given after sixty days, and no pain was elicited.

On the site of the first injection of estrone a large erythematous area about 6 by 4 inches (15 by 10 cm.) developed, which discoloration persisted up to the third month's stay. That this local reaction was not due to the solvent of estrone (peanut oil) was demonstrated by the absence of local reaction on the site of the control injection.

Analysis of the Results of These Tests.—With regard to the preceding tests a series of questions may be asked. Was the pain elicited by the injection of estrone causal or casual? If it is causal, why did not the second injection of estrone produce a reaction? Could the second injection of estrone have been so modified or nullified by the preceding injections of progesterone that no reaction supervened?

Or was the lack of progesterone the factor responsible for the phenomena observed in this case, as evidenced by the cessation of pains after progesterone administration? Or was a disturbance of the complicated estrin-progestin metabolism the cause of the allergy? Or were the observations resulting from these tests purely coincidental, as evidenced by the cessation of the pains at about the same time as during previous admissions?

No specific answers can be given. Any attempt on our part to deduce conclusions on such paltry observations will border on mere suppositions without scientific accuracy. However, the preceding observations, coupled with the association of the pain with pregnancy and the puerperium, may warrant the suggestion that the disturbance in the estrin-progestin metabolism was *partly if not totally responsible* for the allergic manifestations.

SUMMARY

A case of allergic peritonitis is reported. The salient features are: recurrence of symptoms in association with pregnancy and the puerperium; the syndrome of acute abdominal pain during the attacks; the presence of ascites during each attack; eosinophilia in the peripheral blood and in the ascitic fluid; evidences of noninvolvement of other abdominal organs; response of the abdominal pains to the administration of epinephrine; a *strong familial and personal history of allergy*, and an apparent relationship to the complicated estrin-progestin metabolism.

This case may call attention to one form of allergy heretofore unreported.

BENADRYL IN THE TREATMENT OF CERTAIN DISEASES OF THE SKIN

PAUL A. O'LEARY, M.D.
and
EUGENE M. FARBER, M.D.
Rochester, Minn.

In the last year a new drug, beta-dimethyl aminoethyl *benzohydryl ether* hydrochloride (Benadryl hydrochloride[1]) has become available for clinical investigation and, more recently, for therapeutic use. This compound was prepared by Loew and his associates.[2] It belongs to a distinct pharmacologic group and is believed by its originators to have an antihistamine action. Experimentally, it relieves histamine shock and anaphylactic shock in the guinea pig and exerts an antispasmodic action on smooth muscle. It is a white crystalline powder, soluble in alcohol or water, and can be administered orally or intravenously. We have administered Benadryl to a large group of patients who have had dermatoses characterized by cutaneous edema, such as urticaria,[3] acute or early scleroderma including acrosclerosis and atopic dermatitis. It is the purpose of this report to discuss the results obtained in the treatment of these disturbances with Benadryl and to comment on some of the clinicopharmacologic properties of this drug.

URTICARIA

Urticaria, or "hives," is a condition characterized by localized accumulations of fluid in the skin or mucous membranes. It results from temporary pathologic permeability of blood vessels. Angioneurotic edema or giant urticaria is essentially the same process, except that the subcutaneous tissues are involved and the lesions may occur in the mucosa of the nasopharynx, larynx, bronchi or bladder. Whether the condition is urticaria or angioneurotic edema, whealing is the basic pathologic manifestation.

From the section on dermatology and syphilology, Mayo Clinic.

[3] O'Leary, P. A., and Farber, E. M.: Benadryl in the Treatment of Urticaria, Proc. Staff Meet., Mayo Clin. **20**: 429-432 (Nov. 14) 1945.

Acute urticaria which follows the injection of a biologic product or the ingestion of food, drugs and the like may last for a few days to a few weeks and usually subsides spontaneously without treatment. When Benadryl is administered, however, relief of the pruritus usually occurs in twenty to sixty minutes, with reduction of the swelling in from two to six hours. We prescribed Benadryl to be taken by mouth every three to four hours in doses varying from 50 to 100 mg. for 35 patients who had acute urticaria. Twenty of these patients were completely relieved in from one to two days; the condition of 12 was improved, meaning that the pruritus receded and that there were fewer, smaller wheals, and 3 patients were not benefited. Side reactions occurred in 10 of the 35 patients but were not severe enough to warrant discontinuance of Benadryl, although this might have become necessary in several instances if recovery from urticaria had not been so prompt.

Chronic urticaria may last for many years; when it does, the cause is more obscure than that of the acute phase of the disease. Patients who have chronic urticaria often are regarded as suffering from fatigue states, although occasional cases are encountered in which illness is the result of visceral disease. The patient who has hives chronically may be wholly or partially incapacitated because of intense itching, insomnia and disfigurement. Wise and Sulzberger[4] have said, that ". . . despite the most thorough 'work-ups' under conditions of the most perfect collaboration . . . most chronic cases [of urticaria] remain unsolved. They run their mysterious course of months or years, often to cease as suddenly and as unexpectedly as they started."

Treatment on the whole has heretofore been ineffective and has consisted of numerous empiric methods. A review of the histories of 75 patients who had chronic urticaria elicited an array of therapeutic agents which they had received or methods with which they had been treated.

Occasionally, some of these forms of treatment have been of curative or palliative value in individual cases, but no single treatment has been of consistent benefit. Moreover, in the evaluation of any remedy for urticaria, study of a large number of patients is necessary, for the condition often subsides spontaneously. The impressive number and variety of treatments which Benadryl replaces are seen in table 1.

With the recent discovery of drugs which possess an antihistamine action,[5] it is now possible to give striking palliative relief to most patients who have chronic urticaria. Of 75 patients treated, 48 were entirely relieved while they were taking Benadryl, 17 had fewer lesions and less pruritus and 10 obtained no benefit. Substitution of placebos or discontinuance of therapy resulted in prompt recurrence of the lesions. Twenty-five patients, or a third of those treated, complained of varying degrees of side reactions to Benadryl, but only 8 of these reactions were of sufficient severity to justify discontinuance of administration of the drug.

The following 2 cases are reported as typical examples of the response of chronic urticaria to Benadryl hydrochloride.

REPORT OF CASES

CASE 1.—A white woman aged 29, a housewife, consulted the section of dermatology of the Mayo Clinic on July 11, 1945 because of generalized urticaria and angioneurotic edema of four months' duration. Lesions occurred during the day or night and often lasted six to fourteen hours. Frequently swellings occurred in the patient's tracheobronchial tree and produced severe dyspnea. Dietary factors were not involved, and results of numerous skin tests had been negative.

Ten minims (0.62 cc.) of epinephrine taken hypodermically gave some relief, but all other forms of treatment, including rigorous elimination diets, sedative agents and the like, had been valueless. For ten months in 1941 the patient had had the same disturbance, but it had ceased spontaneously after dilatation and curettage, which had been carried out because of the increased premenstrual severity of the urticaria. There was no history of infantile eczema, hay fever or asthma in the patient or in her family.

The patient was a well developed and well nourished white woman with multiple pea-sized to palm-sized urticarial wheals asymmetrically distributed over her arms, trunk and thighs. A severe grade of dermographia appeared after the exertion of linear pressure on the skin. Foci of infection were not demonstrated. Results of physical examination and of extensive laboratory studies were not significant.

Psychiatric care
Lotions, salves, etc.
Skin tests

Vaccines

Escherichia coli
Streptococcus vaccine

One hundred milligrams of Benadryl was prescribed for the patient, to be taken three times a day, after each meal. The patient was seen a week later and stated that she had not had hives since taking the drug. She was advised to discontinue the treatment, which she did, but she returned three days later with numerous lesions on her legs, thighs and trunk. With the resumption of therapy she again became free of all urticarial wheals. After the first month of treatment the amount of Benadryl taken was decreased to 150 mg. a day, with equally effective results. Wheals promptly recurred whenever she discontinued the therapy.

This patient had suffered from hives for four months before an effective palliative remedy was prescribed. She must, however, continue to take Benadryl every day, or the lesions will reappear. To the time of this report, she has taken the drug almost every day for ten months, or a total of approximately eight hundred to nine hundred capsules. The cause of the urticaria could not be found.

CASE 2.—A white man aged 20 came to the Mayo Clinic on May 22, 1945 because of severe angioneurotic edema of seven months' duration. He stated that palm-sized swelling occurred almost every day, involving at various times his eyes, lips, tongue, throat, hands, feet and genitals. The lesions were exceedingly pruritic, often painful and lasted several hours to several days. Past treatment, including the taking of epinephrine, the use of elimination diets, succinylsulfathiazole and other measures, had been valueless.

---

[4] Wise, F., and Sulzberger, M. B.: The 1936 Year Book of Dermatology and Syphilology, Chicago, The Year Book Publishers, Inc., 1936, p. 17.

[5] Mayer, R. L.; Huttrer, C. P., and Scholz, C. R.: Antihistaminic and Antianaphylactic Activity of Some α-Pyridinoethylenediamines, Science **102**: 93-94 (July 27) 1945.

Careful interrogation of the patient and the results of extensive laboratory and physical investigations did not reveal a plausible etiologic factor, but fatigue was considered to be a contributing cause.

The patient was given 50 mg. of Benadryl three times a day for two weeks. During this time he was entirely free of angioneurotic edema. On discontinuance of administration of the drug, there was prompt recurrence of the lesions, but when its administration was resumed he once more remained free of lesions for four weeks. He then, on his own volition, discontinued the therapy. When he was seen at the clinic four weeks later, he stated that urticaria had not recurred.

The foregoing case is of interest in respect to two points. First, it indicates that Benadryl gave striking symptomatic relief; second, it illustrates that urticaria may subside spontaneously.

Benadryl has a wide margin of safety and can be taken for many months in succession without deleterious results. It is just as effective in controlling urticaria in the fourth or fifth month of use as it is in the first. The following 10 cases are illustrative of this.

CASE 3.—A white man aged 41 had had chronic urticaria and angioneurotic edema for eight months prior to registration at the Mayo Clinic. He now takes 150 mg. of Benadryl a day and to the time of this report has been entirely free of lesions for eight months. Discontinuance of administration of the drug results in prompt recurrence of the urticaria. There have been no unpleasant side reactions.

CASE 4.—A white man aged 69 who had had chronic urticaria and angioneurotic edema for two and a half years came to the clinic, where 100 mg. of Benadryl a day was prescribed. He became entirely free of lesions for the first time in two and a half years. Substitution of placebos resulted in the occurrence of new lesions. To the time of this report he has been taking the drug for six months and has not had any side reactions.

CASE 5.—A white woman aged 25 had had urticaria and angioneurotic edema for fourteen months. She remained free of hives only so long as she took 100 mg. of Benadryl three times a day, but she became drowsy after she had taken each capsule. After four months of Benadryl therapy she required only 100 to 150 mg. a day and no longer complained of being drowsy.

CASE 6.—A white woman aged 26 complained of angioneurotic edema and chronic urticaria of six weeks' duration. Three 50 mg. capsules of Benadryl a day suppressed all lesions but produced dizziness, dilated pupils and dryness of the mouth. To the time of this report she has taken 150 mg. of the drug each day for eight months. She reports that when she does not take Benadryl for a day the lesions recur. She still complains of slight dizziness and dryness of her mouth.

CASE 7.—A white man aged 56 came to the clinic because of generalized hives which had occurred daily for thirty years. Innumerable types of therapy had been administered without value. Two hundred milligrams of oral Benadryl each day resulted in complete freedom from urticaria. The patient complained of dryness of his mouth from the capsules. Four 50 mg. capsules controlled the urticaria, three capsules would partially control it, but two capsules would not control it at all. After taking the drug for four weeks, this patient complained of severe drowsiness and was forced to discontinue the medicament.

CASE 8.—A white woman aged 29 who had had urticaria for two years complained of dilated pupils and bradycardia which resulted from taking 300 mg. of Benadryl a day. No lesions were present when this dosage was employed. She remained free of symptoms while receiving 150 mg. of the drug a day and had no side reactions. To the time of this report she has taken Benadryl for eight months and requires from one to three 50 mg. capsules a day. Urticaria reappears if she does not take the drug every day.

CASE 9.—A white woman aged 59 who had had chronic urticaria and angioneurotic edema of nine months' duration received symptomatic relief from the taking of 150 mg. of Benadryl a day for seven months. No side reactions were present at any time. On one occasion angioneurotic edema of the throat was promptly relieved by the taking of 100 mg. of the drug.

CASE 10.—A white man aged 49 who had had urticaria and angioneurotic edema for four months obtained complete relief by taking 150 mg. of Benadryl a day, but he became "jittery" after taking each capsule. To the time of this report he has taken the preparation for five months but still complains of being "jittery" for about one hour after each dose of the drug. Nevertheless, he prefers this reaction to the unpleasantness of urticaria.

CASE 11.—A white woman aged 43 complained of hives of three years' duration. She obtained complete relief from the lesions by taking 100 to 250 mg. of Benadryl a day for eight months. No side reactions were observed during this time, and the drug was as effective in aborting or preventing lesions at the end of eight months of therapy as it had been early in the course of treatment.

CASE 12.—A white man aged 32 stated that for six and a half years he had had hives and swellings in his throat, which occurred almost every day. One hundred milligrams of Benadryl given four times a day made him dizzy and weak. The dosage was decreased to 50 mg. three times a day, with resultant control of the urticaria. The patient has received the drug for six months, to the time of writing, and has been able to decrease the amount to from 50 to 100 mg. a day. This gives him complete freedom from urticaria. In five months, he has reported, he has had only one attack of hives, and he has not experienced any further side reactions to Benadryl.

ATOPIC DERMATITIS

We used Benadryl in the treatment of atopic dermatitis because of the frequent concomitant occurrence of cutaneous edema, white dermographia, hay fever and asthma in this disturbance.

It is difficult to evaluate our results, because Benadryl seldom was the only remedy prescribed. Patients who have generalized eczematoid changes usually are instructed to take soothing baths and to use wet dressings, antipruritic lotions and similar measures. Benadryl was prescribed as an adjunct to other forms of therapy for 25 patients who had atopic dermatitis. It relieved severe paroxysms of pruritus for 8 of the 25 patients. Patients who have atopic dermatitis frequently experience itching more at night than during the day. Thus, if 100 mg. is taken at bedtime and drowsiness results as a side reaction, it is not an unwelcome reaction. If relief from pruritus is not obtained within the first few days there seems to be little justification for continued use of Benadryl. Aside from the fact that the drug decreased the severity of paroxysms of pruritus for 8 patients, we did not observe any other benefits accruing from its use.

PRURITUS ARISING FROM OTHER CAUSES

Benadryl is not an effective antipruritic drug. It afforded relief to only 6 of 38 patients who suffered from itching due to various causes, such as contact dermatitis, jaundice, toxic pruritus, psoriasis, dermatitis herpetiformis, so-called neurogenic pruritus and the like.

SCLERODERMA AND ACROSCLEROSIS

In the presence of scleroderma and acrosclerosis, edema may be the earliest change seen in the skin. Edema produces stiffness and limitation of motion and may last for varying periods before sclerosis and atrophy occur. Because we were able with Benadryl to decrease or prevent the development of edema in the presence of urticaria, it occurred to one of us (O'Leary) that a similar mechanism might decrease the edema which occurs in scleroderma.

Nine patients who had acrosclerosis and 4 who had scleroderma received Benadryl by mouth in amounts varying from 200 to 800 mg. a day. A chief complaint of the acrosclerotic patients was their inability to flex their fingers or to make a fist. During the first two weeks of therapy 7 of the 9 patients who had acrosclerosis were able, because of the rapid disappearance of edema from their hands, to bend their fingers and to make a fist. Sustained benefit, however, was observed in only 2 of these 9 patients. Of the 2 patients who obtained sustained symptomatic benefit from taking Benadryl, one was a 65 year old woman who complained primarily of stiffness and swelling of her hands. After Benadryl therapy alone, increased mobility of her hands developed, and in a week she was able to flex her fingers. She remained without pain or swelling of her extremities for five months, at the end of which period she discontinued therapy. In a short time the swelling, cyanosis and pain returned, but with the resumption of Benadryl therapy she again gained symptomatic relief. At the date of this report she is still doing well. She has had a total of seven months of treatment.

Table 2.—*Side Reactions to Benadryl*

Condition	Patients Treated	Side Reactions
Chronic urticaria	75	25
Acute urticaria	35	10
Atopic dermatitis	25	8
Scleroderma	13	5
Miscellaneous	38	10
Total	186	58 (31 per cent)

The second patient with acrosclerosis who improved definitely was a 24 year old waitress who complained of stiffness and swelling of her face, chest and hands. Small painful ulcers were present on the tips of her fingers. To the time of this report she has received 500 mg. of Benadryl a day for six months. At present the ulcers are healed, the patient is able to make a fist, softening of the skin in the affected areas has ensued, and she is able to work.

TOXICITY

Side reactions of varying degrees developed among 58 of 186 patients (31 per cent) who received Benadryl (table 2). The side reactions in order of frequency were drowsiness, dizziness, weakness and dryness of the mouth. Some patients complained of being "jittery," "on edge," "nervous," "confused," "poorly coordinated," "nauseated" and "excited."

Side reactions usually occur during the first few days after the administration of the drug is begun and frequently diminish in severity or disappear entirely after several weeks of therapy. "Late" side reactions developed among only 10 patients. These occurred for the first time after several months of daily use of the drug. Symptoms of toxicity promptly disappear when the drug no longer is administered. Ten patients were not able to use Benadryl because it apparently caused unusually severe dizziness and drowsiness.

COMMENT

Treatment of urticaria and allied dermatoses should begin with small doses of Benadryl, such as 50 mg. administered three times a day. The amount should be increased gradually until the minimal maintenance dose has been determined. Conversely, patients may require 300 to 400 mg. of the drug a day for several weeks but frequently are able to decrease the amount gradually until smaller doses become equally effective.

Benadryl does not seem to exert a cumulative action, for urticarial lesions promptly reappear when administration of the drug ceases. If relief is not obtained within the first few days, it is unlikely that Benadryl will subsequently be of value, and administration of it should be discontinued. In our ten months' experience with the drug manifestation of cutaneous sensitivity has not been observed, nor is there any evidence to date that it is habit-forming.

Indiscriminate use of Benadryl should be discouraged, for severe side reactions sometimes occur, such as loss of judgment or confusion.

SUMMARY

Benadryl is highly effective in the treatment of acute urticaria, chronic urticaria and angioneurotic edema, but relief is obtained only while the drug is being used. The drug decreases the severity of paroxysms of pruritus for some patients who have atopic dermatitis but is not a potent antipruritic drug. The condition of patients in the edematous phase of scleroderma is temporarily improved; such patients are able, by virtue of suppression of cutaneous edema, to achieve increased mobility in their extremities. Side reactions occurred among 31 per cent of the patients in this study but were severe enough to warrant discontinuance of the administratioin of Benadryl to only 10 patients.

Little Strokes That Go Unrecognized.—In the case of older persons, cerebral arteriosclerosis is perhaps the commonest cause for fatigue and misery and a nervous breakdown. Particularly disabling are the little strokes that so often go unrecognized. Many of them come in the middle of the night. Commonly they are thought to be heart attacks or attacks of Ménière's disease. The gastroenterologist sees many of these patients because so often with the cerebral thrombosis there is a wave of distress which shoots into the abdomen. Often it goes into the thorax, and then the tentative diagnosis may be heart disease. To diagnose the little strokes one must keep thinking of them, and then one may be able to draw forth the typical story of sudden onset and big character change. Often one can get this story only from the family or business associates. Only they will tell of the nervous breakdown, the changes in behavior, the increased irritability, the forgetfulness and the tendency to weeping and depression. The thing to remember is that, with the exception of carcinoma of the pancreas, there is no disease in the abdomen that can quickly change a person's whole character.—Alvarez, Walter C.: What Is the Matter with the Person Who Is Always Tired? *Northwest Medicine,* June 1947.

Clinical Notes, Suggestions and New Instruments

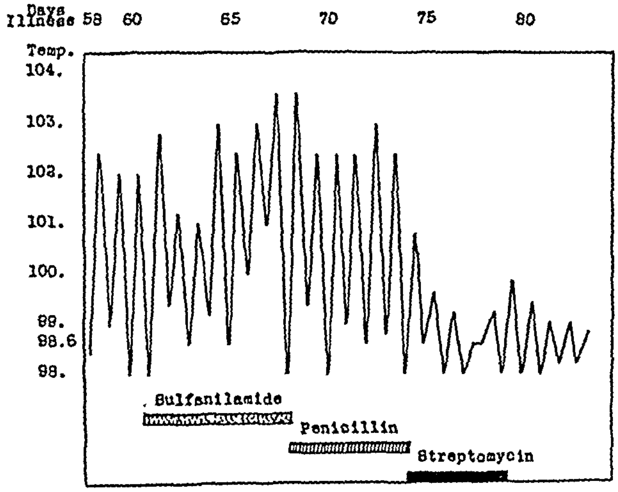
HAVERHILL FEVER DUE TO STREPTOBACILLUS MONILIFORMIS TREATED WITH STREPTOMYCIN

MILFORD H. SPRECHER, M.D.
Elkton, Md.
and
J. R. COPELAND, M.A.
Salisbury, Md.

Haverhill fever, epidemic arthritic erythema, was diagnosed by blood culture in a white man 38 years old, a welder by occupation. Observation began May 25, 1946 and has continued to date. Streptomycin was used by us in the treatment of Haverhill fever for the first time, as far as we are able to determine.

REPORT OF A CASE

History.—B. W., a white man aged 38, while welding in a small compartment of a ship on April 7, 1946, became nauseated, vomited once and had diarrhea for twenty-four hours. He stayed home for two days and then returned to work in spite of weakness, chills, rises of temperature and night sweats. The temperature established no pattern except to rise in the early evening, and this was not a daily occurrence until May 18, when pain in the legs began.



The effect of streptomycin on temperature.

The pain was intense and was located deeply back of the tibias. It was also present back of the knee joints and in the ankles, yet seemed not to involve all these joints at the same time. Swelling of the joints was not noticeable. In the evenings the patient would first notice the feeling of fever, then in an hour or so the pain in the legs, which continued with sleeplessness until late morning. No rash made its appearance. Cough was present with a little expectoration. The weight dropped to 127 pounds (58 Kg.) from 140 pounds (63 Kg.). Moderate urinary frequency was present without dysuria. The appetite was poor, but eating did not lead to an overfilled sensation. The color of the stool was recalled as brown. There was no shortness of breath or swelling of the feet.

The past history was characterized by an attack of diphtheria at the age of 8, subsequent to which valvular cardiac murmurs were noted. At the age of 27 and again when he was 28 he was treated for cardiac decompensation with rheumatic heart disease. However, vigorous activity was in no way limited until his present illness.

Examination.—Examination on June 4, 1946 showed a man of small stature, who appeared moderately ill and apprehensive. His attitude seemed to be that of seeking immobility, and attention directed to his lower extremities was resented. There was no cutaneous eruption at any place on his body. His right ankle looked swollen but was not red and was without extreme tenderness on pressure. Motion was resented in this joint, as well as deep pressure in the calves. Other joints were free of tenderness, swelling or restriction of motion.

The scalp carried a good coat of hair. The face showed numerous scars from acne. There was slight puffiness of the lower eyelids; the pupils were regular and equal and reacted to light. The conjunctivas showed no jaundice, and the palpebral membranes were light pink. The nasal passages were adequate with only slight exudate. Frontal and maxillary sinuses transilluminated. The teeth appeared good. The tongue was slightly coated, the pharynx was normal and the tonsils were small. The right ear drum was dulled.

The neck was not rigid; the thyroid was not enlarged and the trachea was in the midline. There were many shotlike glands in the posterior triangles.

There were two wartlike linear lesions in the right subclavicular region. The lung fields were resonant throughout and the bases descended in both axillas and in the back. Breath sounds showed no changes. The apex beat of the heart was in the seventh interspace on the left side and was slightly vigorous on palpation. The left border of the heart measured 12 cm. from the midsternum. There was a systolic mitral murmur, rather soft in character, that was transmitted to the left axilla. There was a soft systolic murmur at the aortic area. The peripheral arteries were soft. No definite glands could be felt in either axilla. The pulse rate was 98, the temperature 102.4 F. and the blood pressure 120 systolic and 80 diastolic.

There was slight distention of the abdomen and some rigidity of the rectus muscles. The spleen was not palpable. The left lobe of the liver was enlarged to about three fingerbreadths below the costal margin. This area was slightly tender. Some inguinal glands were enlarged. The prostate and the scrotal contents were normal. Superficial reflexes and the tendon reflexes were present and normal.

Laboratory Examination.—On the initial admission on June 4, examination of the blood revealed that the hemoglobin was 66 per cent, the red blood cell count 4,040,000 and the white blood cell count 10,000, with a normal differential pattern. Examination for malaria was negative. No stippling of the cells was seen. Subsequent examinations on June 15, 20, 21 and 27 showed a progressive anemia, the last blood count being hemoglobin 51 per cent, red blood cells 3,000,000 and white blood cells 13,600. The sedimentation rate was reported as 8 mm. (Wintrobe).

The urinalyses were negative on June 4 and 15 but on June 26 showed 4 plus albumin and 50 white blood cells per high power field. The urine cultures at the time of the pyuria showed Staphylococcus albus and Escherichia coli.

Roentgenograms of the chest revealed normal conditions, and stool examinations were negative. The electrocardiogram was normal. The blood Wassermann test was negative. Blood cultures carried out on June 4, 5 and 6 contained Streptobacillus moniliformis.

Physical signs of chronic rheumatic valvular disease suggested the possibility of endocarditis. Undulant fever was suspected until the positive blood cultures of Streptobacillus moniliformis were reported and the negative agglutination reactions for undulant fever were confirmed.

Investigation by the county health officer brought out the fact that the locker rooms where lunches were kept were overrun with rats.

Bacteriologic Data.—The Streptobacillus moniliformis[1] isolated was first noted as similar to bread crumbs, a growth appearing on the sedimented blood cells of a routine blood culture after six days' incubation. It is extremely likely that growth occurred before this time but was overlooked, because in two repeat blood cultures growth was noted on careful observation after forty-eight hours. It was a small, gram-negative bacillary or coccoid organism, rarely producing the filaments that are so characteristic, non-acid-fast and nonhemolytic, which required blood or serum for the maintenance of growth. Growth in serum broth was always from the bottom of the tube and extended up the sides. It was aerobic but was aided in its growth by carbon dioxide. It grew well on chocolate agar and thioglycollate semisolid mediums. It died out rapidly, usually on the third or fourth day in a medium which supported rapid growth. Acid without gas was produced in dextrose and maltose but not in sucrose and lactose. Colonies were discrete, circular and extremely small with raised umbonate centers with crenated edges.

Patient's Agglutination Response to the Organism.—The antigen used was prepared by growing the streptobacillus in serum broth for forty-eight to seventy-two hours, centrifuging at high speed for thirty minutes, decanting, resuspending the sediment in about one third the amount of isotonic sodium chloride solution, killing by subjecting to 52 C. for two hours and diluting to a usable antigen. As stated by Brown and Nunemaker,[2] until the organism has been cultured through fifty or sixty generations it is hard to prepare a homogenous antigen. Since the organism at this time had only passed the twenty-fifth or thirtieth generations it had a tendency to settle after overnight incubation at 52 C. However, it was possible to tell definite agglutination as against settling by resuspending the antigen by shaking. Agglutination tests submitted May 25, May 31 and June 19, 1946 which gave no reaction to Eberthella typhosa O, Salmonella paratyphi B, Brucella abortus, Proteus OX 19 and OX 2 antigens were positive for the Streptobacillus antigen all in the dilution of 1 : 1,280. Several checks were run with negative serums and with serums giving reactions to typhoid and undulant fever antigens, but none agglutinated the Streptobacillus antigen.

Therapy.—While awaiting the report of the blood cultures, sulfanilamide, 0.65 Gm., with sodium bicarbonate, 0.65 Gm., were administered to the patient for seven days. When the Streptobacillus was reported, the administration of penicillin, 30,000 units at three hour intervals was begun and continued for six days. The accompanying chart shows the lack of specificity of penicillin and the dramatic success of streptomycin administered in 0.3 Gm. doses at three hour intervals for five days.

Subsequent Course.—The third dose of streptomycin permanently relieved the pain in the legs, and the temperature remained normal thereafter, except for one day when 100 F. was reached because of pyuria. With the administration of penicillin, the patient's condition had seemed to become more grave.

The liver became more enlarged and decidedly tender on June 22, or about the sixtieth day of the disease, and some fluid seemed to have collected in the patient's abdomen. An albuminuria developed that lasted for another month. It persisted for two weeks after the pyuria had been cleared by the use of sulfathiazole, 0.5 Gm. four times a day.

Cultures of blood taken five days after the administration of streptomycin and again fourteen days later have been negative for any growth.

COMMENT

Haverhill fever is characterized by "an abrupt onset; a rubellaform to morbilliform eruption, chiefly on the extremities, and an inflammation of the joints with marked pain and tenderness." [3] The diagnosis is made by the isolation from blood or from articular fluid of a highly pleomorphic filamentous or spindle-shaped aerobic or microaerophilic gram-negative organism, Haverhillia multiformis, which requires serum for growth in artificial mediums.[4]

Parker and Hudson [5] were responsible for the creation of the name of the organism after study of the cases of Place, Sutton and Willner,[6] who reported in 1926 an epidemic in Haverhill, Mass., of a disease called by them erythema arthriticum epidemicum and Haverhill fever. The organism was the same as that isolated in 1925 by Levaditi and his co-workers [7] from a case of "acute erythema multiformis unassociated with rat bite" and named by them Streptobacillus moniliformis because of its distinctive morphology. Litterer [8] in 1917 obtained an organism from blood cultures of patients with rat bite fever; this he called Streptothrix longus and Streptothrix brevis, and he was the first also to use the term Streptobacillus. Schottmüller,[9] however, in 1914 was the first to describe adequately the Streptothrix which he cultured from the blood of a patient suffering from rat bite fever.

This briefly indicates the confusion attending the organism, when the Streptobacillus moniliformis is described in three languages under three different names and in three different diseases.

It is an apparent normal inhabitant of the nasopharynx of 50 per cent of laboratory rats and of wild rats. It has also been found in pulmonary lesions of rats. It is transmitted through contaminated milk, presumably, and also by the bite of rats. The organism seems to overshadow etiologically Leptospira morsus muris, also known as Spirillum minus, the highly mobile spirillum of uniform morphologic character which causes sodoku,[2] or rat bite fever.

Haverhill fever, as described by Place and Sutton,[3] has arthritis as the most persistent symptom, from the second to the thirteenth day of the disease, subject to remission and recurrences. In addition to definite involvement of the joints there is generalized pain in the legs and arms without local evidence in the joints. Chills usually precede the rash, which was noted in 13 per cent of their cases. Fever is always present, and often there are headache, sore throat and cough. Fever is usually septic, and the temperature returns to normal in one week; but this depends on the degree of articular involvement, and the fever may persist for months.

Treatment of the disease has included use of the sulfonamide compounds and penicillin. The former have been ineffectual, but Altemeier [10] has reported good results with penicillin in cases which were due to the bite of rats and were not Haverhill fever. In experimental animals Heilman and Herrell [11] obtained good results with penicillin. Here again they were dealing with Streptobacillus infections due to the bites of rats.

SUSCEPTIBILITY TESTS

Susceptibility of the Streptobacillus moniliformis to penicillin and streptomycin was carried out by two methods:

Impregnated Filter Paper Method.—No. 1 filter papers were cut into 10 mm. squares, sterilized and wet, in one instance with a solution of penicillin containing 1,000 units, 100 units and 10 units and in the other with a dilute solution of streptomycin. These were dried in a vacuum desiccator over calcium chloride. Serum agar plates were inoculated heavily over the whole surface with a young culture of the Streptobacillus moniliformis and with a young culture of a penicillin-sensitive Staphylococcus aureus. For the penicillin test the different strength papers were spaced across the diameter of the inoculated plates. Since only one strength of impregnated streptomycin paper was used, it was placed in the center of the inoculated plates. Incubation was in a candle can at 36 C., and results were read at forty-eight and seventy-two hours. From the greatest strength of penicillin-impregnated paper the staphylococcus was inhibited for a distance of 15 mm., while the streptobacillus was inhibited for a distance of not over 5 mm. At lower strengths, at which the staphylococcus was inhibited for 12 mm. and 10 mm., the streptobacillus was not inhibited at all. On the streptomycin plate this drug inhibited the growth of staphylococcus for a distance of 10 mm. and that of the streptobacillus for a distance of 17 mm.

Serial Dilution Method.—The medium used was thioglycollate semisolid, which supported a good growth of the streptobacillus at twenty-four hours. Duplicate serial dilutions were made of the two drugs used. One set was inoculated with a drop of a twenty-four hour growth of the streptobacillus, the other with a drop of a twenty-four hour growth of the staphylococcus. All tubes were incubated in a candle can at 36 C. and the results read at the end of twenty-four hours and again at forty-eight hours. The results obtained can best be seen from tables 1 and 2. Roughly speaking, the streptobacillus is sixteen times more resistant to penicillin and thirty-two times more susceptible to streptomycin than is the staphylococcus. In other words, the organism is decidedly resistant to penicillin and extremely susceptible to streptomycin. In the 3 cases reported by Altemeier and others[10] their results showed a slight difference in the susceptibility to penicillin in vitro of 1 of the 3 streptobacilli isolated. Our results suggest that considerable difference in susceptibility might occur in different strains of this organism, just as they do among the staphylococci. One might venture to say that the difference in results obtained in the treatment of infections caused by Streptobacillus moniliformis with penicillin could be due to the susceptibility or resistance of the strain involved.

CONCLUSION

We would emphasize that: 1. Streptomycin is definitely an effective agent against Haverhill fever. 2. Wild rats can infect food or milk in storage lockers. 3. An alert technician can isolate Streptobacillus moniliformis, though he may not be forewarned of its presence. 4. In vitro tests indicate that the streptobacillus causing Haverhill fever is highly susceptible to streptomycin therapy but resistant to treatment with penicillin.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following report. HOWARD A. CARTER, *Secretary.*

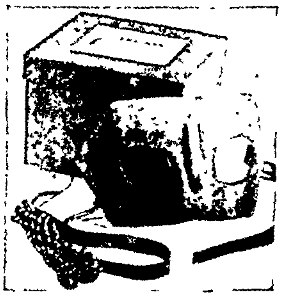
VAN VECHTEN THERMASK ACCEPTABLE

Distributor: Don Parkin Company, 5601 Hollywood Boulevard, Hollywood 28, Calif.

The Van Vechten Thermask provides a means of applying heat to the frontal area of the head and cheeks by controlled electric current. In appearance the appliance resembles a mask, which is attached to the head by means of a ribbon.

The device is constructed as follows: Nichrome wire is wound on a canton flannel base and attached to this base by the addition of a plastic solution (vinyl chloride) This coil is held between two cloth shells, which are also impregnated with the plastic, and the three pieces are joined together by the external application of heat and pressure. The finish is a flock application sprayed onto a urea resin synthetic enamel, making the unit moisture proof with high dielectric properties.

The device was investigated clinically by the Council. This investigation revealed that, for its limited purpose of applying heat to a restricted area, satisfactory results were obtained. This form of applying heat is no more beneficial than the use of an infrared lamp, an electric pad or any other form of applying external heat except that it may be more convenient. The device is useful in furnishing a uniform gentle heat. The Thermask carries the seal of the Underwriters' Laboratories, Inc.



Van Vechten Thermask.

The Council voted to accept the Van Vechten Thermask for inclusion in its list of accepted devices.

ACCEPTANCE OF RADIANT HEATERS

In considering radiant heat generators for inclusion in its list of devices acceptable for use in physical medicine the Council notes that, whereas the so-called "sunlamps" [1] emit a narrow spectral band of ultraviolet radiation of short wavelengths that have a specific biologic action, the radiant heaters of so-called "infrared lamps" emit a wide spectral band of radiation (predominantly of infrared rays) no part of which has a specific biologic action. Moreover, the depth of penetration of these rays into the body is superficial (1 to 10 mm.). Hence these infrared lamps cannot be used as an effective substitute for the diathermy apparatus.

It is further noted that there is no great difference in the spectral quality and the total intensity of the radiation emitted by infrared generators such as bath room heaters and those used in physical therapy. The main differences are the more elaborate adjustable mounting and the more costly finish which, for convenience in operation and for appearance as an office fixture, are incorporated in the professional models.

---

[1] Acceptance of Sunlamps, J. A. M. A. **102:** 42 (Jan. 6) 1934, **114:** 325 (Jan. 27) 1940.

Two distinct types of infrared generators are available:

Type 1.—Tungsten or carbon filaments, heated to high incandescence, in a glass bulb that is mounted at the focus of a concave reflecting mirror; or the filament is inclosed in a conical bulb (of clear or red glass) in which the reflecting mirror is built on the inside of the funnel-shaped part of the glass inclosure. The maximum of spectral energy emitted by the gas-filled tungsten lamp is in the region of 10,000 angstroms. About 30 per cent of the total radiation emitted is of wavelengths that can penetrate deeply (1 to 10 mm.) into the skin.[2]

Type 2.—Infrared radiators of the second type consist of an electrically heated solid rod, or a resistance wire (usually of nickel-chromium alloy) embedded in, or wound on, a refractory material, usually porcelain. They are mounted in a concave bowl-shaped reflector and are operated at a red heat, with a maximum of spectral energy emission in the region of 20,000 angstroms to 40,000 angstroms in the infrared (see chart 1 of footnote 2). The bath room heaters in common use are of this type.

In contrast with ultraviolet generators there are no special hazards involved in the use of thermogenic generators (infrared lamps) by the public. The action of infrared radiation is thermal and instantaneous, producing a painful burning sensation if the intensity is too great. Hence there is no excuse for any one getting burned if ordinary care is used.

One of the main considerations involved in the acceptance by the Council of radiant heaters is compliance with the Fire Underwriter's Safety Code; including a wire screen placed over the lamp (in case of breakage) to prevent hot particles falling on the patient if the lamp is suspended over the bed.[2] The high powered (approximately 500 watts or more) infrared generators are intended to be operated at some distance (3 feet or more) from the bed. To reduce the hazard from burns and fire by contact, the reflector should be double walled to prevent overheating. The main fault with many of the infrared heaters is overheating of the porcelain socket that supports the heating unit, with the resultant oxidation of the metal parts and the lead wires at the juncture with the reflector.

The radiant flux (intensity) along with the axis of these lamps varies greatly with the diameter of the reflector, which in turn determines the area that is to be irradiated.

For example, the intensity of a prescription model unit, rated at 220 watts, in a reflector 9 inches in diameter at a distance of 36 inches was practically the same (30,000 to 40,000 microwatts [3] per square centimeter) as that of a 600 watt unit in a reflector 18 inches in diameter; but the area that was uniformly irradiated was much smaller.

In view of the foregoing considerations the Council will accept prescription model units consisting of an infrared radiator mounted on a mechanically stable pedestal stand (adjustable from 3 to 5 feet in height) that permits projection of the beam of radiation in various directions. For use over a bed the infrared lamp shall be provided with a safety wire screen. Furthermore, until a more satisfactory criterion for acceptability of infrared lamps is needed, the Council on Physical Medicine takes into consideration the energy input in the lamp as follows:

In type 1 (glass enclosed tungsten or carbon filaments, heated to high incandescence) the energy input shall not be less than 250 watts.

In type 2 (resistance units heated to a bright red incandescence as described [2]) the energy input shall not be less than 220 watts, preferably 550 watts or greater, depending on the intended use.

In applicator lamps the rated energy input shall be not less than 50 watts, to insure sufficient intensity without making contact with the affected part under irradiation.

In view of the plethora of infrared radiators on the market and the continuing increase in novelties in heating units, it is relevant to note that the Council's acceptance of a device is not to be construed as an aid in sales promotion.

Each new heating device will be considered on its merits.

[3] Average summer sunshine is 1 gram calory per minute per square centimeter—70,000 microwatts per square centimeter.

Council on Foods and Nutrition

ACCEPTED FOODS

The following foods which are used primarily for restricted diets have been accepted as conforming to the Rules of the Council on Foods and Nutrition of the American Medical Association. James R. Wilson, M.D., *Secretary.*

FOODS FOR SPECIAL DIETETIC PURPOSES

The American Dietaids Company, Inc., Yonkers, N. Y.

Dietician Brand Butterscotch Flavor Pudding, containing rice flour, Irish moss extract, salt, artificial flavors, U. S. certified food color, soluble saccharin, dulcin and tricalcium phosphate.

Analysis (submitted by manufacturer).—Moisture 8.0%, ash 9.50%, fat (ether extract) 0.40%, protein (N × 6.25) 5.0%, carbohydrates 60.0%.

Calories.—2.80 per gram; 79.52 per ounce.

Dietician Brand Lowmay Salad Dressing, containing frozen egg yolks, salt, dulcin, cider vinegar, hydrogenated vegetable oil, water, spice oils and corn starch.

Analysis (submitted by manufacturer).—Moisture 77.40%, fat 12.0%, protein (N × 6.25) 1.0%, total carbohydrates 9.0%, total acidity as acetic acid 0.68%.

Calories.—1.50 per gram; 42.60 per ounce.

PLAN FOR ACCEPTANCE OF JUICES

In order to encourage the production of fruit juices containing high natural levels of vitamin C, the Council accepts orange juice in which at least 40 mg. of ascorbic acid per hundred cubic centimeters of juice is conserved.

The following product meets the standards and rules established by the Council for fruit juices.

James R. Wilson, M.D., *Secretary.*

FRUIT JUICE—ORANGE JUICE

The Cal-Grove Products Company, Los Angeles, Calif.

Cal-Grove Frozen-Fresh Orange Juice.

Analysis (submitted by manufacturer).—Soluble solids 13.5%, calories 0.40 to 0.50 per gram, ascorbic acid 43.4 mg. per hundred cubic centimeters.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

Austin Smith, M.D., *Secretary.*

MANNITOL HEXANITRATE (See New and Nonofficial Remedies, 1946, p. 336).

The following dosage form has been accepted:

The National Drug Co., Philadelphia

Tablets Mannitol Hexanitrate: 30 mg.

ASCORBIC ACID (See New and Nonofficial Remedies, 1946, p. 631).

The following additional dosage form has been accepted:

Mead Johnson & Co., Evansville, Ind.

Tablets Ascorbic Acid: 50 mg.

TABLETS BUFFERED PENICILLIN (See The Journal, March 22, 1947, p. 851).

The following dosage form has been accepted:

E. R. Squibb & Sons, New York

Tablets Sodium Penicillin-G: 50,000 units and 100,000 units with 0.5 Gm. of trisodium citrate as a buffer.

PECULIARITIES OF THE CIRCULATION IN THE LUNGS AND HEART

In a recent Shattuck Lecture Dock[1] states that more progress has been made in the past thirty years in the quantitative study of the circulation of viscera than had been achieved in the previous three centuries. He predicts that the introduction of the vascular catheter and the use of radioactive isotopes will open a vast program of study of the circulation in various organs of normal and diseased men. While much of this advance was made possible by new technical methods, some of the data have been obtained by the injection or perfusion of organs post mortem by a technic that was possible even in the days of Harvey. A description of the circulation of an organ to be complete must include an estimate of oxygen needs, basal and maximal, the capacity of the vascular bed and the volume flow under varying conditions. The rates of flow during life in some organs can now be measured with accuracy.

Because the lungs occupy a large space and blood circulates through them at a relatively low pressure, posture greatly alters the quantity of blood in the apex and base or in the dorsal and ventral parts. Posture also alters the volume flow of blood through the lung. On reclining, the blood that fills the veins below the diaphragm is no longer held back by gravity, and the effective venous pressure, the quantity of blood in the lungs and the output of the heart are increased, the last by as much as 30 per cent in some subjects. Venous blood in the lungs must return to the left ventricle. Because of the effect of gravity on this flow, venous pressure at the bases is 20 to 30 cm. (expressed in its equivalent of water) greater than at the apex of subjects in the orthopneic position. When the patient is in the right semirecumbent posture the venous pressure in the lateral and basal parts of the right lung is 10 to 20 cm. higher than in any part of the left lung. These simple facts are of paramount importance in explaining the frequency of right-sided hydrothorax and of basal pulmonary edema, particularly in cases of cardiac failure. With the rise in venous pressure the flow of lymph also increases, and the removal of bacteria or dusts is most rapid at the base of the lungs. At the apex of the lung, not only is the venous pressure low but the arterial inflow is compromised when adults are sitting or standing. The fall in pressure along the course of the arteries is more definite on the right side because the right pulmonary artery arises at an acute angle from the direction of the flow in the pulmonic conus and pursues a tortuous path around the aorta. Consequently, Dock says, the apical fourth of the left lung and the apical third of the right lung can have practically no blood flow for two thirds of each day in the life of sedentary people. Antibodies formed by the body or antibiotics given parenterally will not reach this zone, and dusts, bacteria and toxins cannot be removed effectively from it when lymph flow ceases. As all this creates ideal conditions for tubercle bacilli, it is not remarkable that tuberculosis flourishes in this region. The high incidence of tuberculosis in congenital pulmonary stenosis, which greatly lowers pulmonic arterial pressure and the low incidence of active tuberculosis in mitral stenosis, with pulmonic pressure several times normal, supports the thesis that arterial inflow is of crucial importance.

The effect of gravity on the lungs thus explains the remarkable efficacy of rest flat in bed in the treatment of apical tuberculosis as contrasted with other types of the disease. Antibiotics will be least effective in reaching apical lesions when patients are allowed to sit up most of the day.

The peculiar relations of the pulmonary circulation to gravity are of great practical effect in the management not only of pulmonary tuberculosis but also of congestive heart failure. While the orthopneic posture makes life tolerable in heart failure it makes recovery impossible in apical tuberculosis.

The human heart probably never uses more than 0.1 cc. per gram of oxygen per minute; during vigorous activity the amount used is believed to be about 0.06 cc., a quantity that can be supplied by a blood flow of 1 cc. per minute. This leaves the venous blood still half saturated with oxygen and with an oxygen tension sufficient to allow diffusion of oxygen into the center of a muscle fiber twice the diameter of those in a greatly hypertrophied heart. Cardiac hypertrophy is a mechanism of great adaptability. In arterial hypertension of gradual evolution the left ventricular wall becomes thicker, but the diastolic capacity does not increase. While the muscular fibers are thicker, they are no longer than normal. However, when increased output must be maintained, as in hyperthyroidism or anemia, the muscle fibers grow longer and the chamber becomes more capacious.

---

[1] Dock, William The Clinical Significance of Some Peculiarities of the Circulation in the Kidneys, Liver, Lungs and Heart, New England J. Med, May 22, 1947.

Does the coronary bed adapt itself to the growth of the myocardium? The perfusion of hearts with oil has yielded data on this important question. The coronary perfusibility per gram per tissue decreases as hearts grow from infancy to maturity. Dock found that the flow at ages 66 to 85 was 30 per cent less than at ages 25 to 40. It has been found that in cardiac hypertrophy without coronary disease the blood flow is more than adequate to provide oxygen in excess of the needs of the thickest fibers. The flow per gram also decreases in hypertrophied hearts, but it appears merely as a smooth extension of the curve of the decline in the normally growing heart up to maturity. While the coronary bed adapts itself to the needs of the heart, it is peculiarly liable to atherosclerosis, especially in populations using diets (such as ours) which have a large meat, milk and egg content. Nearly a fifth of the sedentary men of North America die because of vulnerability of the epicardial branches of the coronary system. Even when the aorta and the rest of the arteries are in faultless condition coronary occlusion may occur, particularly in men under 50 years of age. The coronaries at birth have thicker intimal layers than any other vessels of similar size in the body, and this natural thickness of intima increases throughout life. In newborn infants, Dock found that the males had far more striking intimal cushions than the females. This anatomic peculiarity may be the cause of the higher mortality and the earlier onset of coronary disease in males. The predilection of atherosclerosis for the coronary arteries in men and in certain families may therefore be due to an anatomic anomaly present at birth. Fortunately, the adaptability of the coronary circulation under stress imposed by disease is such that normal cardiac function may be maintained for years after the occlusion of the largest arteries in the heart.

VITAMIN A AND BONE GROWTH

Mellanby[1] demonstrated in animal experiments that deficiency of vitamin A in the diet of growing animals causes widespread degeneration of tissue in the nervous system. Of the cranial nerves the olfactory, the optic, the trigeminal and the auditory are reported as especially liable to suffer destructive changes. The dysplasia of bone which resulted from vitamin A deficiency and which was responsible for the grave effects on the nervous system could be largely, if not entirely, explained by altered osteoclastic and osteoblastic activity. The bone changes that result from vitamin A deficiency were demonstrated by Mellanby to be reversible. Soon after the addition of the vitamin the osteoclasts and osteoblasts again become active in their normal positions, the osteoclasts especially being numerous and active, as if making a special effort to remove the superfluous bone laid down or not absorbed in the period of vitamin A deficiency. The bones tend to return to normal.

The dysplasia due to vitamin A deficiency appeared to Mellanby to involve more or less all the bones of the body. Vitamin A, he asserts, plays a controlling part in the molding of all bones. Vitamin A when given in proper amounts insures that bone growth or bone molding proceeds along correct, predestined and safe lines; when the vitamin is deficient, growth continues in an orderly but wrong way, which leads to injury or even destruction of the nervous tissue and ultimately to the death of the animal. The restoration of vitamin A to the diet of the deficient animal quickly brought about a response in the bone cells directed to correct the dysplasia resulting from the absence of the vitamin. Mellanby points out that brain and cord cavities and the foramens which allow the passage of nerves to and from the central nervous system must enlarge to accommodate the growth of the nervous system. If vitamin A is deficient in the growing puppy, bone growth is so changed that the skull cavity and the spinal cord enlarge inadequately and irregularly and the foramens may even become smaller, with destructive results which may include destruction of the olfactory, optic, trigeminal and auditory nerves of the posterior routes of the spinal cord.

Wolbach and his co-workers confirmed in rats the destruction of nervous tissue by bone pressure produced by vitamin A deficient diets, but their interpretation of the cause of the bone pressure differed from that of Mellanby. Wolbach presents evidence[2] which indicates that remodeling sequences attending growth of bone are induced by a factor elaborated in the maturation of epiphysial cartilage cells. He stresses that increase in size of most bones during growth of the skeleton is by endochondral bone formation, for which purpose, until growth is completed, cartilage persists at epidiaphysial junctions. Thus growth of a long bone is accomplished by continuous proliferation of cartilage cells arranged in columns on the epiphysial side and concurrent degeneration of matured cartilage cells on the diaphysial side. The spaces which result from the degeneration and disappearance of the cartilage cells at the diaphysial ends of the columns are penetrated by capillaries accompanied with osteoblasts which are responsible for the deposition of bone matrix on the exposed cartilage matrix. Multiplication, increase in size, maturation and death of cartilage cells are therefore necessary sequences in normal skeletal growth. Preservation of conformation demands continuous remodeling involving resorption of bone where reduction of size is necessary and new deposition of bone from endosteal and periosteal sources to preserve continuity of structure. The deposition of bone by cells of endosteum and periosteum Wolbach refers to as appositional bone formation. In general, endochondral bone formation sets the pace and the pattern of skeletal growth. According to Wolbach, endochondral bone growth in vitamin A deficiency ceases before the growth rate of the animal as a whole is seriously affected. The result of the disproportionate growth of bone and central nervous system is overcrowding of spinal canal and cranial cavity and paralysis resulting from mechanical pressure on brain, spinal cord and nerve routes. Cessation of endochondral growth is not the sole effect of vitamin A deficiency on young bones; remodeling ceases and appositional bone formation continues at different rates in locations which vary with the species but which are in conformity with each normal growth pattern.

[1] Mellanby, Edward: Vitamin A and Bone Growth: The Reversibility of Vitamin A Deficiency Changes, J. Physiol. **105**: 382 (Jan.) 1947.

[2] Wolbach, S. B.: Vitamin A Deficiency and Excess in Relation to Skeletal Growth, J. Bone & Joint Surg. **29**: 171 (Jan.) 1947.

Wolbach showed in his experiments that appositional bone formation continued and in certain locations became excessive after endochondral bone formation had ceased in vitamin A deficient animals. Apparently Mellanby and Wolbach agree as to the effect of vitamin A deficiency on bone growth in young animals; but while Mellanby explains this effect by the influence of vitamin A on the activity of osteoblasts and osteoclasts, Wolbach stresses that the effect of vitamin A deficiency is on the epiphysial cartilages and endochondral bone growth.

Current Comment

TOXIC ACTION OF EMETINE HYDROCHLORIDE ON THE HEART

Recently Dack and Moloshok[1] reported 9 cases of amebic dysentery in which toxic cardiac manifestations developed following treatment with emetine hydrochloride. The total doses of emetine varied from 7 to 22 grains (0.45 to 1.42 Gm.). The principal signs of toxic effects on the heart were dyspnea and tachycardia on mild exertion, fatigue and electrocardiographic changes generally involving the T waves. Because of the variation in the dosage of emetine hydrochloride which produced toxic cardiac effects, the investigators believe that there are individual differences in susceptibility to the drug or in the rate of its excretion. Signs of toxic effects were generally apparent in the neuromuscular and gastrointestinal systems before evidence of harm to the heart was manifest. These investigators believe that maintaining the patient at absolute bed rest throughout the course of treatment would decrease the frequency of toxic manifestations from emetine hydrochloride. The pulse rate should be recorded at frequent intervals daily, since tachycardia may be the first clinical sign of toxic effects on the heart. Daily examination and questioning of the patient would help to detect any possible evidence of toxicity, such as fatigue, diarrhea, dyspnea on exertion, muscular tremors or weakness and dizziness. They also advise that an electrocardiogram be taken before treatment is instituted and after administration of the fifth grain of emetine, and that the drug be promptly discontinued if significant changes are found. They believe that in the majority of cases of amebic dysentery the therapeutic effect is as good from the administration of 5 to 7 grains (0.32 to 0.45 Gm.) as with the higher doses sometimes employed. They also recommend that if evidence of amebiasis persists after the first course of treatment—and evidence of toxicity of emetine hydrochloride is not obtained—a rest period of at least a month should intervene before the resumption of treatment. Finally, they say that emetine hydrochloride should not be used in the presence of suspected organic heart disease and should be employed with great caution in patients who are anemic and debilitated.

EXCERPTA MEDICA AND OTHER ABSTRACT PUBLICATIONS

Excerpta Medica, a new publication with headquarters in Amsterdam, Holland, proposes to provide abstracts in English of every article appearing in every available medical journal in the world. These abstracts are to be issued in the form of fifteen separate sectional journals, each journal devoted to a definite field in clinical or theoretical medicine. This huge task will require some 3,000 specialists all over the world and 400 supervising editors. In each section either one or two volumes will be completed each year and on completion of each volume an index will be included. All published abstracts will bear the signatures of the specialists who prepared them. Abstracts will be numbered in the issues and, to facilitate ready and rapid reference, will be classified in the index both according to the author's name and according to the subject. The first issue offered is section XIII, devoted to dermatology and venereology. The British Medical Association is issuing monthly reports of abstracts in two forms, one dealing with internal medicine and one dealing with surgery, gynecology and obstetrics. It is also understood that Julius Springer Verlag, Berlin, is considering a revival of its zentralblätter and berichte.

PROGRESS IN INTERNATIONAL HEALTH ORGANIZATION

Real progress was made in international organization for health at the International Health Conference[1] held in New York June 19 through July 22, 1946. While all previous international health organizations have been purely informational and advisory in character, the new World Health Organization, under its constitution, will have the right to require certain annual reports from members, as well as to adopt conventions and regulations in specified fields such as sanitation, quarantine, disease, nomenclature, diagnostic standards, biologic products and pharmaceutic products. When the signatures of twenty-six member nations are affixed this constitution will come into force.

Medical Economics

MEDICINE AND ECONOMICS

ERNEST E. IRONS, M.D.
Chicago

Current views of the nature and content of what is called economics are as varied and often as bizarre as are some of the plans devised by idealists for the improvement of the human race and the establishment of Utopia. Some are based on misinformation or on partial information, others on prejudice with a minimum of knowledge.

Economics has been defined as a classless scientific study of the means by which people earn their living and of how they spend their income.

Up to a few years ago, few physicians knew or even thought much about questions of supply and demand, of competition, of financial systems, of theories of government. We along with most other citizens went about our businesses or professions, content to live under a democratic government. In spite of its easily recognized faults, it suited us and allowed us the personal freedom and opportunity which we enjoyed, but little appreciated, until we were threatened with their loss.

Now, after a period of war which required sacrifice of life and treasure, regimentation and suffering from the disruption of business and of living necessarily incident to total war, we have added difficulties of class demands and finally proposals that government take over the practice of medicine.

Shall we follow blindly the proposers of theories without consideration of whither they lead, or shall we look into history, where we may find the answers to the same problems in previous decades and centuries? Winston Churchill once remarked "The longer you can look back, the farther you can look forward. This is not a philosophical or political argument —any oculist will tell you this is true."

Much discussion of late has concerned what may be termed the internal economics of medicine: the prospective oversupply of specialists, which, it would seem, we may safely leave to the laws of supply and demand; the overcrowding of hospitals, and the denial of staff appointments to general practitioners in some places. These are faults which can be cured by a liberalization of hospital policies and the adoption of a less selfish attitude by certificants of special boards. The economics of medicine follow the same laws as do general economics, but with the most important modifying influence of the personal relation of physician to his patient.

Medical economics in the larger sense is closely integrated with the general economics of nations. In times of prosperity or of relative political quiet the proposers of revolutionary plans do not find popular support. Periods of stress, resulting from reduction of the opportunity of people to secure adequate food, clothing and other satisfactions of living, prepare the way for the acceptance by the people of theories and procedures of government which sometimes result in desirable reforms but more often bring ruin or delay the accomplishment of remedial measures because they violate economic laws.

The continuing realinements of civilization which we like to think of as advancing, the outcropping of national interests, and revolutions made possible and ultimately produced by the abuses of previous governments have brought into being other forms of government, which may be acceptable or possibly desirable in the countries of their origin but which are repugnant to our own. We here have no wish to dictate the form of government to be established elsewhere, but we do resent attempts from abroad and by malcontents at home to undermine our own democracy with the purpose later to substitute an unacceptable socialist régime. The present proposal to socialize medicine is one step toward this end, directed at medicine because it is vulnerable by reason of defects in distribution and because medical deficiencies are closely related to economic distress.

Some of the advocates of these social changes are sincere in their desire to help the underprivileged but lack the foresight or information, readily available from a study of the economics of history, to appreciate the ultimate results of their well intentioned efforts to aid the downtrodden. They become the ready tools of another group, who use these humanitarian impulses to further a deeper laid plan for the destruction of our form of government. The people are offered a program which promises to give them something they have not had before, whether it be Roman corn or paper money or medical service, and they seize on the new, not considering what they will lose or what the effect will be on their personal liberty or ultimately on their own government.

The unexpected results of new laws are often more significant than those anticipated by the framers of these laws. In our recent labor shortage many men preferred to receive their $20 dole than engage in urgent and legitimate work. In efforts to provide a buffer against adversity in the form of an unemployment dole, men have been encouraged to assume that the world owes them a living. A Negro maid in our community announced that she would take a vacation. Asked why, she said "I like my job, and I get good pay, but I figure that these times won't last and if I don't spend my money I'll have a bad time getting on relief."

We hear now no voices raised in favor of the destruction of food products, the slaughter of little pigs, the plowing under of food crops. Yet only a few years ago the advantages of an economy of scarcity were loudly proclaimed, to a large extent by the same group who would now regiment medicine by governmental edict.

Remarkable is the facility of such people to support unsound measures by fallacious and uneconomic arguments; then when the inexorable laws of supply and demand and the requirements of simple humanity demonstrate their failure quickly they shift to other and equally unsound ground, leaving the wreckage of their previous fiascos for others to clear away as best they can.

Under paternalistic laws more and more is done for people so that their individual responsibility grows less and less and they become finally mere pawns of the state. In order to make such a system operate, dictators are created. There is still retained a figment of representation, but the system operates by compulsion and personal responsibility is lost. Lord Elton, historian and fellow of Queen's College, Oxford, and himself a member of the British Labor Party, in speaking[1] of the relation of England to her colonies in 1770, well said "Later experience has repeatedly shown that representation without responsibility is the most dangerous of halfway houses to democracy."

COMMUNISM IN THE COLONY OF VIRGINIA

A communal system is no stranger in this country. It was tried and failed under John Smith in the colony of Virginia. Its operation is described in a report of Sir Thomas Dale, successor to Capt. John Smith, to the British Crown, quoted by Lord Elton.

"The early colonists had labored under two crippling disadvantages, communal ownership and its inevitable consequence, martial law. . . . The business of all proved to be the business of none." Men would not work for the common store as they would have worked for their own families, and Smith and his immediate successors had to drive their reluctant fellows with savage threats and punishments.

Condensed from an address delivered to the Columbia Medical Society, Columbia, S. C., April 14, 1947.

1. Lord Elton: Imperial Commonwealth, New York, Regnal and Hitchcock, 1946.

"The effects of a very partial introduction of private property under Sir Francis Dale were startling and immediate. Each man was given 3 acres of his own but still had to work eleven months out of twelve for the general store. Even so the lazy became industrious overnight.

"When our people were fed out of the common store and laboured jointly together, glad was he who could slip from his labour or slumber over his taske; he cared not how, nay, the most honest among them would hardly take so much true paines in a weeke, as now for themselves they will doe in a day; neither cared they for the increase, presuming, howsoever the harvest prospered, the general store must maintaine them, so that wee reaped not so much Corne from the labours of thirtie as now three or foure doe provide for themselves. . . .

"Gradually but only gradually the authorities in England came to realize that communal ownership and compulsion must go hand in hand. . . ."

EFFECT ON QUALITY OF SERVICE

That socialized medicine interferes with the physician-patient relationship is self evident by the recognition of advocates of socialized medicine of the necessity of providing a panel. The most shrewd advocates of socialized medicine have failed utterly in their contention that their plan will not interfere in this fundamental confidential relation of doctor to patient. It always has and always will. Indeed, this interference is part of their plan, although the more ardent advocates will not admit it.

The delegation of dictatorial power to one man, even though he may be advised by a council appointed by the same authority, is urged because, it is stated, there will be a tremendous amount of detail to be handled. This is true, and it will require also an enormous addition to our already swollen army of civil servants, much greater than was required for temporary wartime control of production and prices.

Physicians have up to now been individualists; they do their best work on a competitive basis. If the physician is alert, well trained, honest, proud of his profession and its achievements, he will strive continually to improve and give better service, and he is rewarded by the gratitude of his patients and in increase in his clientele and emoluments. To the degree that he is poorly prepared, slothful and loses his incentive to improve, he will do less creditable work. He will be limited by the deadly average of attainment, loss of initiative and dependence on a paternal government, which has always been the next step downward in socialistic governments of history. The removal of the individual incentive is fatal to progress, and human nature is the same, irrespective of occupation. Socialized medicine will reduce the quality of public service as it has in modern governments elsewhere.

Many social injustices and inequalities remain to be corrected. These become more evident as our general standard of living rises from decade to decade, but the remedying of these faults should not be made the occasion for destruction of past gains. In medicine, inadequacies in medical care are closely interlocked with general economic deficiencies. Understaffed and economically poor communities and areas require individualization of treatment, and a plan which will be efficient in one region may not work in another with a different local ideology and economy.

EFFECTS ON DEMOCRACY

While these effects on medical service to the people are serious enough, the less obvious and temporarily more remote effects of a program of socialized medicine on our government are a still greater threat to our national welfare.

A national plan by which government would take over the practice of medicine implies uniformity and loss of personal initiative. Uniformity, whether it concerns the administration of full medical care or of full employment, invokes the sovereign power of the state. Invoking these inherent powers of government to change this and that can lead only to the destruction of democracy and of personal liberty and free enterprise and to the institution of a dictatorship. This inevitable result has come to governments throughout all history from Greece, Rome, Florence down to postrevolutionary France and Nazi Germany. But it is argued that the present plans for government controlled medicine do not envisage any sweeping attack on democracy. At the same time it is averred that an extensive system of bureaucratic control will be necessary to make the program effective. The establishment of such uniform control would be a long step toward authoritarianism more certain in its effect than the legalization of the first issue of paper securities by the French Assembly in 1789.

UNIFORMITY—GOOD OR BAD

Uniformity of itself is not good nor is it bad, considered apart from its effects in the special field in which it is applied. There are many fields of community and national life in which uniformity of action is economically necessary, and these have resulted from science and invention; they are part of what we call the advance of civilization and permit the rise in standards of living. Mass production and the division of labor with the aid of machinery have made possible the enjoyment of comforts and shortened the hours of labor. Most householders do not maintain their own supplies of gas or electricity; if, however, such facilities are not available, they may still light their houses with kerosene lamps or candles. In recent years the gas cylinder and the local air or gas power plant have brought these conveniences to rural areas. The problems of supply of raw materials and of expense vary in different communities according to availability of fuel and the exigencies of climate, and so uniformity is limited by practical considerations. At the same time the householder is under no compulsion to employ them unless he so wishes.

In medicine, rules such as those for quarantine to prevent the spread of disease, for the handling and dispensing of food supplies, for dealing with epidemics have been found by experience necessary in order to do for the individual what he cannot do for himself, and for this purpose local, state and national health departments have been created. In all these, methods have been devised to deal with populations *en masse* for the prevention of disease, and uniformity of method is necessary for their accomplishment.

In education it is recognized that illiteracy is a threat to the life of the state. The welfare of the nation is best served by a system of public schools which can be maintained only by general taxation, under laws administered by the individual states of the Union. The problem of education is general; that of illness is individual. Some states are less able economically than others to maintain current standards and need help, but this need whether educational or medical must not be made the occasion for an invasion of the rights of states by federal bureaucracies.

Uniformity is thus good so long as it makes possible the attainment of desirable ends. Even here uniformity might be bad if it attempted to make all procedures for public utilities the same without regard to climate, natural resources or qualities of populations and also failed to consider that the economic requirements, financial status and abilities of a population today may be different tomorrow. From the beginnings of our government in the early colonies, diversity to meet local conditions and wishes of the citizens has been the rule, rather than uniformity. In the words of Woodrow Wilson, "There was no invariable pattern but everywhere on the contrary a spontaneous adjustment of political means to place and circumstance."

Uniformity provided by a national law for government practice of medicine would not correct the deficiencies in needy areas whose problems require varying treatment: at the same time it would impose an inferior quality of service on all.

MONOPOLIES

The institution of a government monopoly of medical care will produce the same results as have monopolies of the essentials of life in the past, whether it be the accumulation of grain by an Egyptian pharaoh or the acquirement of lands and vast sources of wealth by a Roman tyrant or the monopoly of business by Louis XIV. We have already seen in our own national life the ill effects of great business monopolies: the Sherman Antitrust Act was passed to prevent the stifling of competition. Monopoly of labor through unions originally designed to obtain justice and fair treatment for labor has now resulted in profit to a few of one class, to the detriment of a still larger class of labor, by denying them free opportunity to work. Monopolies whether of capital or of labor work to the benefit of their sponsors only so long as they are exceptional—when they become general they are destructive of the general welfare and ultimately destroy their creators. For this reason socialists and communists favor monopolies in business and in medicine as factors forwarding their own objectives.

Governmental monopoly of any product results in governmental dispensing of that product to its subjects. The recipients of government largesse look more and more to the government and, like the early colonists of Virginia, work less and less and invite the compulsion which precedes socialistic slavery and ultimate dictatorship.

The seriousness of some economic thinking in our own time was summarized in a recent political utterance ascribed to a counselor now dead and startling in its unashamed frankness: "We shall spend and spend, and tax and tax, and elect and elect."

Care of people by a paternalistic government results in loss of their sense of personal responsibility, first to participate in government, and later to make any effort to contribute to the general welfare.

In urging the theory of the right of a citizen to be cared for, social workers, betrayed by their own idealism, forget that this citizen has also an obligation in a democracy himself to contribute to the general welfare. Without insistence on this obligation, democracy fails.

We are just now emerging from a period of governmental regulation and centralization under bureaucracies made necessary by total war. This period, in which we have become somewhat inured to regimentation, is especially dangerous to our democracy. Socialist and totalitarian governments grow by steps, slowly at first, but with a steadily increasing tempo and always by deluding the people into the belief that the new will be better than what they already have. Government monopoly whether in business or in medicine inevitably leads to the abuse of power and deterioration of quality of service.

Governmental regimentation of medicine would give the American people an inferior rather than a better quality of medical service. What is even more vital, such regimentation would be another long step toward the destruction of free enterprise and of American democracy. As we love our country we shall exert our every effort as individually responsible citizens to maintain the freedoms which are characteristic of America, and the liberty that makes our country the land of the free, the home of free enterprise and of opportunity.

122 South Michigan Avenue.

Coming Medical Meetings

Alaska Territorial Medical Association, Fairbanks, July 28-30. Dr. William J. Blanton, Juneau, Secretary.

American Association of Obstetricians, Gynecologists and Abdominal Surgeons, Hot Springs, Va., The Homestead, Sept. 4-6. Dr. James R. Bloss, 418 Eleventh St., Huntington 1, W. Va., Secretary.

American College of Surgeons, New York, Waldorf-Astoria Hotel, Sept. 8-12. Dr. Paul B. Magnuson, 40 E. Erie St., Chicago 11, Secretary.

American Congress of Physical Medicine, Minneapolis, Hotel Radisson, Sept. 2-6. Dr. Richard Kovacs, 2 E. 88th St., New York 28, Secretary.

American Congress on Obstetrics and Gynecology, St. Louis, Municipal Auditorium, Sept. 8-12. Mr. Karl S. Richardson, 24 West Ohio St., Chicago, Business Manager.

National Medical Association, Los Angeles, Aug. 18-22. Dr. John T. Givens, 1108 Church Street, Norfolk 10, Va., Secretary.

Nevada State Medical Association, Reno, Sept. 4-6. Dr. Moreton J. Thorpe, 17 N. Virginia St., Reno, Secretary.

Oregon State Medical Society, Portland, Sept. 4-6. Dr. Thomas S. Saunders, 1020 S. W. Taylor St., Portland 5, Secretary.

Southeastern Dermatological Association, Knoxville, Tenn., Hotel Andrew Johnson, Aug. 31. Dr. A. H. Lancaster, 608 W. Main Ave., Knoxville, Secretary.

Utah State Medical Association, Salt Lake City, Sept. 11-13. Dr. Ray T. Woolsey, 610 McIntyre Bldg., Salt Lake City 1, Secretary.

Washington Letter

(From a Special Correspondent)

July 16, 1947.

Sanitation Survey by U. S. Public Health Service

The U. S. Public Health Service has reported that a minimum expenditure of $7,834,581,000 is required to improve American water supplies and waste disposal facilities to protect the public from filth borne diseases. Sanitary engineering division of the department bases the estimate on a national survey described as "the most complete inventory of basic sanitary needs ever compiled for the nation." This figure was described as the minimum required to reduce incidence or potential incidence of such diseases as dysentery, diarrhea and typhoid. Surg. Gen. Thomas Parran's comment is that "a sanitary environment for every one is a basic requirement of a national health program." The report stated that waterworks construction, sewage facilities, rural sanitation and garbage collection were required.

Latin American Pediatricians Attend Three Day Congress

A delegation of 414 Latin American pediatricians and several hundred American doctors attended the three day Pan American Congress of the American Academy of Pediatricians. The congress was organized to give Latin American pediatricians an opportunity to consult with the academy's United States membership. Three American doctors were made honorary members of the Latin American division of the American Academy: Joseph S. Wall, Washington, D. C., Henry F. Helmholtz, Mayo Clinic, and Clifford Grulee, Evanston, Ill. Drs. Grulee and Wall also received the Carlos Finlay award for promoting intercontinental advance of pediatrics.

Dr. Parran Prefers Murray Bill to Taft Health Measure

Surg. Gen. Thomas Parran of the U. S. Public Health Service said in a statement prepared for a Senate Public Welfare subcommittee meeting that the health service prefers the Murray Health Insurance bill to that submitted by Senator Taft. The Murray bill would set up a national system of compulsory health insurance to finance medical services for some 85 per cent of the population through a pay roll tax. The Taft bill asks Congress to provide 200 million dollars annually for each of five years to aid states in setting up medical care programs for low income families. Edward F. Poss, Toledo, speaking for the Fraternal Order of Eagles, testified that the Taft bill was "a forward stride in solving some of the health problems," whereas Dr. Allan M. Butler, professor of pediatrics, Harvard Medical School, advocated the Wagner-Dingell bill.

Committees Agree on Federal Cancer Research Fund

House and Senate conferees tentatively agreed on the 1½ billion dollar appropriation bill of the Labor Department's Federal Security Agency for 1948. The measure includes $14,000,000 in federal aid for cancer research and would also allot funds for research on streptomycin. The House had originally approved $17,328,000 for both programs, and the Senate reduced this to $12,000,000.

Doctors Can Go to Canal Zone to Study Malaria

Medical personnel of the District National Guard who want the training can take a twelve week course in malariology at Fort Clayton, Panama Canal Zone. Special courses in various phases of military medicine can be taken at the Army Medical Center in Washington and at army hospitals and medical centers at Denver, Atterbury, Ind., and Fort Sam Houston, Texas.

Health Precautions Planned for Bikini Resurvey

Capt. Christian L. Engleman, U. S. Navy, will serve as project officer under Capt. Thomas H. Hederman, U. S. Navy, who will command a scientific resurvey of Bikini atoll this summer to determine long range effects of atomic bomb tests made there last year. Captain Engleman will coordinate radiologic health and safety plans.

Bureau of Information

LOCATION OF PHYSICIANS

Virginia Shuler
Chicago

This is the fifth of a series of charts showing the trend in locations of physicians from April 1946 to January 1947.

"The distribution of physicians in New Jersey is quite satisfactory. There is no appreciable shortage of physicians in any rural county. There is little evidence of migration of physicians, at least from within the state. The difference in figures pertaining to physician population 1946 and 1947 does not represent migration but rather the return of physicians from military service, most of whom returned to their original location. There has been a moderate increase in physician population in our urban areas The physician population in rural counties is now at its prewar level, with no appreciable increase.

"New Jersey is a compact, industrial state We do have what we consider rural counties, but they are not the type of rural counties contained within many other states. Our farms are mostly of the small, family type farm, not the large farms common in Western states, and all are located within a reasonable distance of centers of population For these reasons the rural health problem is not a major problem in New Jersey

"Our chief hospital need is facilities for the care of the chronically ill. This need is in no way due to lack of appreciation of responsibility or obligation on the part of the profession but to the lack of appropriations to cover the cost of such institutions. We have one county, a rural county, Hunterdon, without a voluntary general hospital. For several years there has been a trust fund available in this county for the construction of a hospital, but at present the population of the county does not feel that a hospital is necessary. They are accommodated in the hospitals of surrounding counties, namely Warren, Somerset and Mercer. There is one point in the county which is 20 miles from a general hospital, the greatest distance of any point in the state from a general hospital.

"A plan for state financial aid to our municipalities is available through New Jersey Municipal Aid Administration to all municipalities in the state for medical care of the indigent. Participating municipalities under this plan at present represent 90 per cent of the state's population. The only large municipality not accepting state aid but handling the problem entirely at its own expense is the city of Hoboken.

"In addition, at a state level, are the following agencies providing categorical assistance including medical care: the New Jersey Commission for the Blind, the New Jersey Crippled Children's Commission, the New Jersey State Board of Children's Guardians, the New Jersey Rehabilitation Commission, New Jersey Old Age Assistance Commission and New Jersey Workmen's Compensation Commission. Through the state department of health are operated Baby Keep Well Stations and Venereal Clinics in each large municipality.

"Over 900,000 persons are enrolled in Hospital Service Plan of New Jersey, the New Jersey Blue Cross Plan, serving employed groups in every county throughout the state, with the cooperation of two hundred hospitals under contract with the plan as cooperating hospitals. Over 90,000 persons are enrolled in Medical-Surgical Plan of New Jersey, the nonprofit prepayment plan organized by the Medical Society of New Jersey, serving employed groups throughout the state with the cooperation of over 3,400 participating physicians"

Norman M. Scott, M D., Executive Assistant,
Medical Society of New Jersey,
31 Clinton Street, Newark 2, N. J.

No Areas in Connecticut requesting general practitioners.

"This state has more physicians than before the war and a slightly increased estimated population. There was a large in-migration of physicians in the months just after military demobilization, and this continues in a lessened degree. The greater proportion of these in-migrants were veterans who had practiced in the metropolitan New York area before the war. A few physicians can still be located in this state but only in carefully selected areas. There are many openings in full time public employment, no part time. Specialists in pediatrics, obstetrics, ophthalmology and otolaryngology, American board diplomates or equivalent, can be considered and some rural openings are apparent."

CREIGHTON BARKER, M.D., Secretary,
The Connecticut State Medical Society,
258 Church Street, New Haven 10, Conn.

No areas in Rhode Island requesting general practitioners.

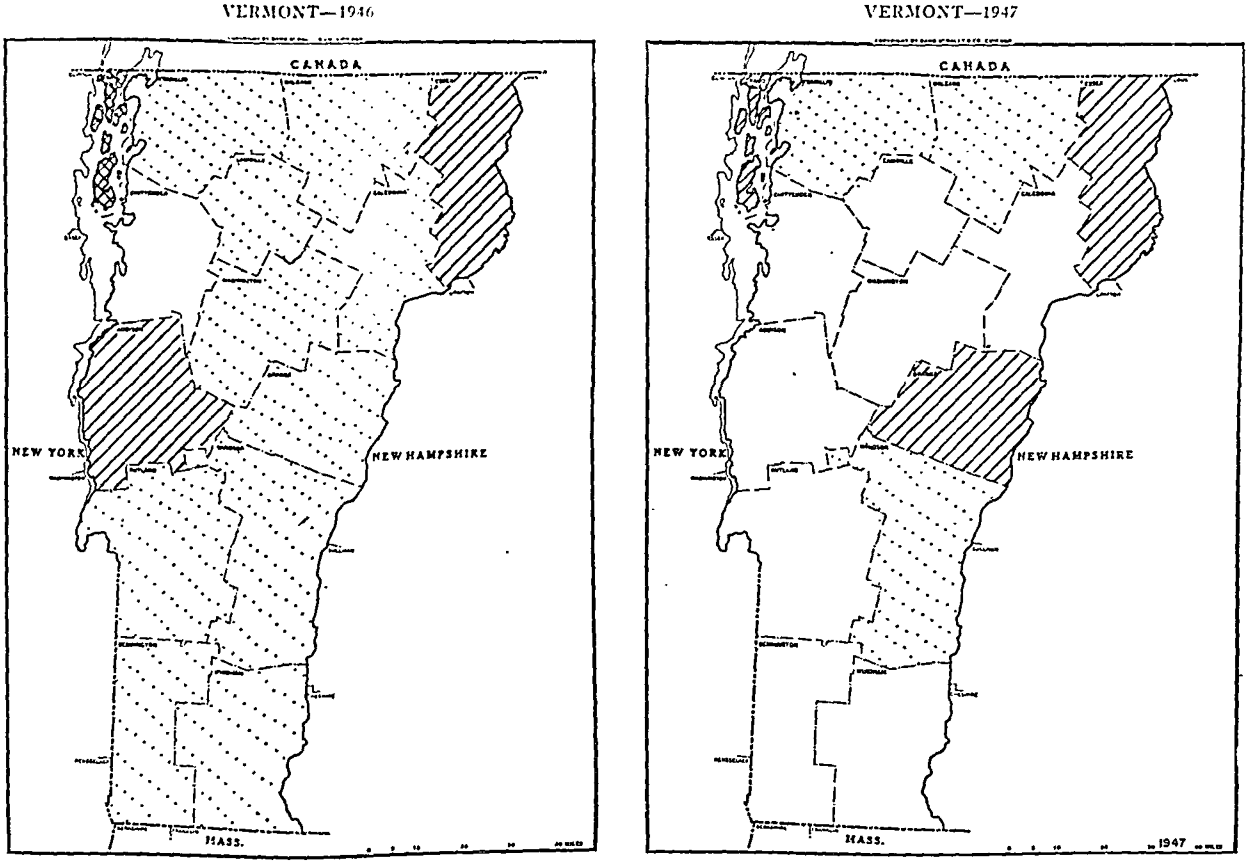
"Because of its geography, Rhode Island is ideally equipped to provide adequate medical care and facilities conveniently to all its residents. No resident is beyond 15 miles from a hospital, and with paved roads crisscrossing the area, transportation is swift and convenient.

"The physician population, as in every state, centers about the large cities. As Rhode Island is better than 92 per cent urban, the situation is ideal. There is no appreciable rural health problem, as physicians can easily move into the limited rural districts from the urban centers or have patients brought to the cities.

"There has been little migration of the physician population due to the war. A few physicians have settled in other states, but their loss has been more than compensated by the arrival here of many young men returned from the armed forces plus several men moving to Rhode Island from other states.

"Successful financial programs have been completed for additional hospital facilities which include the construction of a five million dollar new Rhode Island Hospital. Plans are under way for another new hospital in the state in Kent County, and the Veterans Administration is now erecting a 400 bed hospital close to the center of Providence."

MR. JOHN E. FARRELL, Executive Secretary,
Rhode Island Medical Society,
106 Francis Street, Providence 3, R. I.



VERMONT—1946

VERMONT—1947

Population, based on 1943 estimated Census figures, per active physician (excludes teaching, research, hospital administration, public health and state hospitals) by county.

Key: Physician-population ratio by county: plain area 1-999, dotted area 1,000-1,499, striped area 1,500-2,999, checked area 3,000 and over, solid black area no doctor.

Areas in Vermont Requesting General Practitioners

County	Town	Population
Franklin		29,601
Orange		17,048
Windsor		37,862

"While Vermont, with 398 active physicians to 359,231 population, has a ratio statewide of 1 physician to every 903 people, there is not an even uniformity of this ratio throughout the state, the more rural areas having a somewhat lower ratio of physicians to population. There has been relatively little migration of physicians in Vermont within the past year, but there has been an increase of active practitioners by 39, generally speaking graduates of the University of Vermont College of Medicine who had practiced a year or two in local communities before the war and who have returned to those places.

"We believe that probably the primary reason for our being able to maintain as satisfactory distribution of physicians as we have is the tendency for young men and women here in Vermont to attend the College of Medicine at the University of Vermont and return to their home communities to practice. The secondary reason would be the availability of hospital facilities in most areas. As a partial solution to the economic side of the problem of practice in rural areas, we are hopeful for results from the New Hampshire-Vermont Physician Service, sponsored by the Vermont State Medical Society, which is conducting enrolment campaigns on a community basis, which in our state means that the rural population will have an opportunity to participate."

Mr. John W. Brownlee, Executive Secretary,
Vermont State Medical Society,
128 Merchants Row, Rutland, Vt.

Official Notes

MUTUAL NETWORK BROADCASTS WILL NOT CLOSE

The summer season brings the cessation of broadcasts on the network of the National Broadcasting Company, but the Mutual Broadcasting System program will continue until November 17.

"Doctors—Then and Now," broadcast in cooperation with the National Broadcasting Company, was exceptionally well received by state medical societies, local radio stations and lay listeners and received a first award[1] in its class from the Institute for Education by Radio held at Ohio State University, Columbus, May 2-5. This program was based on regional broadcasts with participation of local medical societies and the origination of speakers at local radio stations in twenty-five areas of the continental United States. It dealt with medicine in the early years of the American Medical Association's hundred year history as compared with medicine today. Twenty-five physicians selected by state medical societies participated in the program.

The Mutual program "Stephen Graham—Family Doctor" is intended to portray to the lay listener some of the difficulties, problems, perplexities and heartbreaks of the physician, as well as his ethical and professional attitude toward patient, community, fellow practitioner and his profession. It is relatively light in educational medical features, since its purpose is to interpret the doctor rather than to educate the public in medical facts. This program too has received wide acceptance from radio stations, physicians and the public.

Extensive network broadcasting is costly. Although time is generously donated by the networks, the program costs must be assumed by the Association, and these are considerable. The Board of Trustees has authorized arrangements to be made for suitable sponsors who will join the Association in rendering public service through radio. This policy became effective in May, and thus far no programs have been sponsored commercially.

The American Medical Association wishes to express to the National Broadcasting Company and the Mutual network its appreciation for cooperation in the broadcasting of these two successful public service programs. To the Columbia Broadcasting System and the American Broadcasting Company, as well as National and Mutual, the Association extends its appreciation for liberal and friendly cooperation in broadcasting important features of the recent centennial meeting at Atlantic City.

Medical Legislation

STATE LEGISLATION

Alabama

Bill Passed.—S. 112, which passed the senate June 25, proposes the enactment of a law to regulate the handling, sale and distribution of **barbiturates.** The proposal would require prescriptions for barbiturates to be made only by a pharmacist on the original prescription of a person licensed to prescribe and administer barbiturates.

California

Bills Passed.—A. 1833, which passed the assembly June 12, to amend the labor code, proposes to define the word physician so as to include **optometrists** when relating to medical services rendered under the workmen's compensation act. A. 2352, which passed the assembly June 3, to amend the health and safety code, proposes to authorize a **cemetery authority** or a licensed funeral director to permit an autopsy of any remains in its custody on the receipt of a written authorization of a person representing himself to be the surviving spouse, a surviving child or parent, a surviving brother or sister, any other kin or person who has acquired the right to control the disposition of the remains, or the coroner or other duly authorized public officer. The proposal would also provide that the cemetery authority or licensed funeral director is not liable for permitting or assisting in making an autopsy pursuant to such authorization unless it has actual notice that the representation therein is untrue. S. 1259, which passed the house June 16, proposes the enactment of a chapter of the health and safety code for the purpose of licensing, inspecting and **regulating public and private establishments** which render to handicapped persons medical advice, diagnosis or treatment, physiotherapy, any form of muscle training, massage, etc.

Bills Enacted.—A. 2428, which has become chapter 867 of the Laws of 1947, to amend the business and professions code, authorizes licentiates of other states to act as resident or assistant resident physicians and **surgeons in state hospitals** for a period of not exceeding one year under certain circumstances. S. 808, which has become chapter 705 of the Laws of 1947, to amend the health and safety code, requires every licensed physician and surgeon or other person engaged in prenatal care of a **pregnant woman,** or attending such woman at the time of delivery, to obtain a blood specimen of such woman at the time of the first professional visit or within ten days thereafter and to submit such sample to an approved laboratory for a laboratory test for syphilis.

Nebraska

Bill Enacted.—L. B. 250, which was approved June 9, 1947, provides for the licensing, inspecting and regulating of hospitals and related institutions within the state and provides for the creation of a **hospital licensing council.**

New Hampshire

Bills Passed.—H. 370, which passed the senate June 18, proposes the enactment of a hospital survey and construction act requiring a **survey of hospital facilities** within the state and the preparation of a program for the construction of additional needed facilities. The proposal also requires the appointment of an advisory hospital council and authorizes the state board of health to apply for and accept federal funds for assisting the state in its hospital program. H. 371, which passed the senate June 18, proposes the enactment of a **hospital licensing law.** H. 448, which passed the senate June 12, proposes to require every physician attending a pregnant woman for conditions relating to the pregnancy to take or cause to be taken a sample of blood of such woman at the time of the first examination and to submit such sample to an approved laboratory for a standard **serologic test for syphilis.** H. 456, which passed the house June 23, proposes the creation of a **mental hygiene commission** to manage and conduct mental hygiene clinics primarily for the psychiatric and psychologic study and treatment of such children as may be committed to its care.

Wisconsin

Bill Introduced.—S. 19, to amend the law relating to **the mentally infirm** and mentally deficient persons, epileptics, inebriates and drug addicts, proposes that the term "examining physician" as used in the act should mean one who is entitled to use the designation M.D.

Bill Passed.—S. 509, which passed the house June 12, proposes to authorize cooperative associations to establish and operate **nonprofit plans for sickness care,** including hospital care, for members through contracts with physicians, medical societies, hospitals and others.

Bills Enacted.—S. 105, which has become chapter 255 of the Laws of 1947, is a hospital survey and construction act requiring a survey **of hospital and health facilities** in the state and the preparation of a program for the construction of additional needed facilities. The law requires the appointment of an advisory hospital council and authorizes the state board of health to apply for and receive federal funds to assist in such survey and construction program. S. 156, which has become chapter 209 of the Laws of 1947, relating to the **licensing of osteopaths,** requires applicants for a license to practice osteopathy to have completed at least twelve months' internship in a reputable osteopathic hospital or its equivalent. S. 446, which has become chapter 269 of the Laws of 1947, requires all physicians and hospital authorities **to report deaths, homicides, suicides,** etc. to the sheriff, police officer or coroner of the county where such death takes place.

GOVERNMENT SERVICES

ARMY

ARMY TO BUILD RESEARCH CENTER

What is planned to be a great research center will be built for the Army Medical Department at Forest Glen, Md., near Washington, D. C., the War Department announced June 22. The initial cost is estimated at about $40,000,000. The Army District Engineer will supervise construction. The project will consist of a 1,000 bed general hospital, the Army Institute of Pathology, the Army Medical Museum and Center Administration building. Central Laboratory Group buildings and the Army Institute of Medicine and Surgery. A working library, quarters for the staff and an animal farm are included in the plans.

The new center will have close relationship to the Walter Reed Medical Center, the Naval Hospital, the medical schools of the District of Columbia and the proposed new District Medical Center, and it will cooperate with the Bureau of Standards, the National Institute of Health and the National Research Council.

Plans for the hospital building provide that 200 beds shall be specifically designated for research activities of the various institutes and central laboratories. However, they will remain an integral part of the hospital for service and patient care. The plans call also for a gymnasium, bowling alleys, swimming pool, auditorium, post exchange, post office, bank and game rooms, included in, or directly connected with, the hospital building.

The Institute of Pathology building will house the Department of Pathology, the American Registry of Pathology and the Army Medical Illustration Service Extensive facilities for experimental research and teaching in pathology will be provided. The building will be connected with the Army Medical Museum and with the Central Laboratory Group. All research activities of the various groups will be correlated and the expanded Central Laboratory Group will serve research and teaching activities of all institutes.

The Administration Building will provide facilities for the administration of the entire center and will house the Army Medical Museum, the main auditorium, the research library and certain graduate teaching facilities.

The Central Laboratory Group will provide research and graduate teaching facilities for the entire center. These will be constructed as the need for them grows, the first being devoted to the service of the Institute of Pathology

The Institute of Medicine and Surgery building will house the departments of Research Medicine, Research Dentistry, Veterinary Medicine, Research Surgery, X-Ray and Radiation and Preventive Medicine.

The center will bring together various medical units now scattered in various parts of the United States.

The architect-engineer contract for the proposed "Army Medical Research and Graduate Training Center" has been awarded jointly to New York and Washington firms as joint venturers.

NURSES NOMINATED FOR REGULAR ARMY COMMISSIONS

The President has sent to the Senate for confirmation the names of seventy-three nurses who have been nominated for permanent commissions in the Regular Army nurse corps. This is the first increment selected for commissions under the new law approved April 16. The nurses nominated have been serving on active duty in the Army, many of them for many years. The new appointment clarifies their status in the Regular Army. The ranks recommended for these nurses vary from the rank of Colonel to that of First Lieutenant, and included in the list is Col. Florence A. Blanchfield, who during the war was chief of the nursing division in the Surgeon General's Office and who is nominated for a permanent rank of Lieutenant Colonel.

ARMY AWARDS AND COMMENDATIONS

Brigadier General Elliott C. Cutler

The Oak Leaf Cluster to the Distinguished Service Medal has been awarded to Brig. Gen. Elliott C. Cutler, M. C., A. U. S., of Boston, for exceptionally meritorious service to his government in a duty of great responsibility from October 1942 to May 1945. The citation explains that, as chief surgical consultant, Headquarters European Theater of Operations, he was responsible for the development of adequate care of all wounded and injured in the theater, and to meet this great responsibility General Cutler developed and promulgated policies, instituted training programs, developed channels of free interchange of medical and surgical knowledge between medical officers of all Allied nations and by constant inspection of all echelons assured the highest standard of surgical care. General Cutler was a source of inspiration to the hundreds of surgeons at whose hands the American soldier received the finest care the world has ever seen. Dr. Cutler graduated from Harvard Medical School in 1913 and entered the service in World War II in July 1942.

Colonel Joseph F. Sadusk Jr.

The Typhus Commission Medal has been awarded to Col. Joseph F. Sadusk Jr., M. C., A. U. S., of New Haven, Conn. Colonel Sadusk rendered exceptionally meritorious service in connection with the United States of America Typhus Commission as executive officer of the special commission sent to the Southwest Pacific in September 1943, which commission conducted original investigations in New Guinea from October through December 1943. Colonel Sadusk had responsibility for most of the administrative matters of a scientific expedition working under campaign conditions in the Dobodura area at a time when scrub typhus was a disease of paramount military importance. He also made original and valuable contributions to the knowledge of the sources and mode of spread of scrub typhus, to the clinical characterization of the disease and to methods of treatment. His many sided contributions to the work of this commission assured its success and added new knowledge on the control and treatment of scrub typhus. Dr. Sadusk graduated from John Hopkins University School of Medicine in 1935 and entered military service in March 1942.

Colonel Hubert T. Marshall

The Legion of Merit has been awarded to Col. Hubert T. Marshall, M. C., A. U. S., who served in various capacities in the procurement of medical supplies and later as commanding officer, Army Medical Purchasing Office, from September 1943 to September 1945. He is recognized in the citation as having made a significant contribution to the successful accomplishment of the Medical Department's mission in World War II. During the period of Colonel Marshall's responsibility for procurement, many important items, such as penicillin and Japanese B encephalitis vaccine, were produced by industry for the first time. He played a significant role in the securing of an even flow of medical supplies without which the high standards obtained in the maintenance of the health of the Army and the care of casualties would not have been possible. He dealt with the many intricate problems of medical supply with courage, outstanding professional skill and a loyal devotion to duty. Dr. Marshall graduated from the University of Louisville School of Medicine in 1932 and entered the military service in December 1934.

Lieutenant Colonel Robert P. Rogers

The United States of America Typhus Commission Medal has been awarded to Lieut. Col. Robert P. Rogers, M. C., A. U. S., of Greenwich, Conn., whose citation mentions the meritorious service which he rendered in connection with the work of the United States of America Typhus Commission during the epidemic at Naples and in southern Italy in the winter of 1943-1944. At that time he was on duty with the Allied Control Council. When his services were made available to the commission, he was placed in charge of the immunization section for the administration of typhus vaccine for the protection of individuals against infection. Through his efficient handling of this section, Lieutenant Colonel Rogers contributed to the success of the typhus control program in southern Italy. Dr. Rogers graduated from Harvard Medical School in 1925 and entered the military service in August 1942.

Major Richard P. Custer

The Army Commendation Ribbon has been awarded to Major Richard P. Custer, M. C., A. U. S., of Philadelphia. The citation read as follows: While on duty at the Army Institute of Pathology from Nov. 27, 1942 to Jan. 23, 1946 his outstanding professional skill and devotion to duty contributed in large measure to the professional success of the Army Institute of Pathology, especially as it is concerned with diseases of the blood-forming tissues and the lymphatic tumors. His studies and research have contributed to our knowledge of these diseases, which proved so important in the military service. Dr. Custer graduated from the Jefferson Medical College of Philadelphia in 1928 and entered the military service in November 1942.

Captain David Hochman

The Bronze Star Medal has been awarded to Capt. David Hochman, M. C., A. U. S., of Brooklyn, who as an assistant to the chief of professional services and surgery at the prisoner of war camps in Osaka, Japan, devoted untiring effort to improving the welfare of fellow captives from April 1944 to July 1945. The citation states that despite his own illnesses he performed services which did much to maintain the health and morale of his comrades. Dr. Hochman graduated from the School of Medicine, Royal Colleges of Edinburgh, Scotland, in 1939 and entered the military service in July 1941.

PUBLIC HEALTH SERVICE

THE ENLARGED CANCER CONTROL PROGRAM

With the passage of legislation bringing next year's budget of the National Cancer Institute, Bethesda, Md., to the all time high of $14,000,000, the U. S. Public Health Service announces plans for an expanded attack on the cancer problem.

Under authority of the Public Health Service law and the appropriation act, support may now be extended to universities to assist in developing greatly expanded cancer research and training programs. The law also supports the acquisition of land and construction of buildings when urgently needed. Under a provision of the act, funds for cancer research and training grants remain available until spent.

Four million dollars of the increase in the budget will go to cancer control, the program administered through the states to increase the effective use of present methods of diagnosing and treating cancer. The cancer control program will place emphasis on the improvement of cancer detection, diagnostic and treatment facilities, the development of refresher courses for doctors, the establishment of adequate statistical services on cancer and the setting up of a cancer control units in state health departments.

In connection with the expanded program Dr. Harry Eagle has been appointed director in charge of research within the institute and Dr. David E. Price in charge of cancer research grants. Dr. Austin V. Deibert also joins the program in charge of cancer control. Dr. Eagle comes to the institute from Baltimore, where he was director of the Laboratory of Experimental Therapeutics, a joint project of the U. S. Public Health Service and the Johns Hopkins School of Hygiene. He has made important research contributions in immunity and serologic tests for syphilis. Dr. Price was formerly in the Research Grants Division of the National Institute of Health, and Dr. Deibert was in charge of cancer control before its recent transfer to the Cancer Institute from the Bureau of States Services of the U. S. Public Health Service.

OFFICERS RELEASED FROM SERVICE

U. S. Public Health Service headquarters reports that the following medical officers have been terminated, inactivated or retired and directed to proceed to the city opposite their names:

Boyd, Dewitte T., S. A. Surgeon (R), Hermiston, Ore.
Card, William J., S. A. Surgeon (R), Chattanooga, Tenn.
Holloman, Alfred L., Surgeon, Frederick, Okla.
Jenkins, Edward C., Surgeon, Pinehurst, N. C.
Koplin, Allen N., S. A. Surgeon (R), New York.
Reiter, Adolph F., Surgeon (R), McKeesport, Pa.
Stanulonis, Stanley W., Surgeon (R), Shenandoah, Pa.

CLOSE MARINE HOSPITAL

According to an announcement by the Surgeon General May 20, the U. S. Public Health Service decided to close the 90 year old Marine Hospital at Evansville, Ind., June 30. The decision was based on the findings of a special board that the hospital had operated at only 50 per cent capacity for the last two years, that patient costs are excessive and that the two wings are fire hazards.

MISCELLANEOUS

VOCATIONAL REHABILITATION PROGRAM

More than 160,000 disabled civilians have been prepared for and placed in paying jobs since the civilian vocational rehabilitation program was expanded four years ago, director Michael J. Shortley announced on the fourth anniversary of the legislation which led to the establishment of the Office of Vocation Rehabilitation. The vocational rehabilitation program through which these civilians became wage earners and tax payers was maintained at an average cost of about $300 per rehabilitated case. The total annual earnings of the disabled men and women who were rehabilitated in the 1946 fiscal year were estimated at about $11,600,000 when they contacted the state agencies; after rehabilitation the rate of annual earnings of these workers —excluding family workers and farmers—was an estimated $56,300,000, or an increase of almost 400 per cent. Public Law 113 amended the original law so that mentally handicapped civilians became eligible for state-federal vocational rehabilitation services, as well as the physically disabled. It also provided authority for the use of medical, surgical and psychiatric treatment to reduce or remove job handicaps resulting from physical or mental disability—a provision which was lacking in the original law.

SALE OF SURPLUS GOVERNMENT PROPERTY

About $1,500,000 worth of pentothal sodium is being offered for sale by the War Assets Administration at new low fixed prices up to July 28. The pentothal sodium is in 0.5 and 1 gram ampules, packed in boxes of twenty-five ampules of the anesthetic and twenty-five ampules of sterile distilled water. Each case contains twelve boxes, and the price f. o. b. is $50 per case for the 0.5 Gm. ampules and $80 for 1 Gm. ampules.

Regional Office, 404 South Wabash Avenue, Chicago 5. Sale of hypodermic needles. Sale opens July 21 and is continuous.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CALIFORNIA

University to Expand Medical Center.—The University of California, Berkeley-San Francisco, has purchased 90 acres of land for the contemplated $30,000,000 expansion of its San Francisco Medical Center on Parnassus Heights. Half of the funds needed for the projected expansion have been provided by the state legislature, and plans are nearing completion for a new medical sciences and hospital building.

Tuberculosis Survey in Chinatown.—The San Francisco Tuberculosis and Health Association and San Francisco and state departments of public health are carrying out a tuberculosis case finding program in San Francisco's Chinatown area. X-ray equipment from the state department of public health has been set up in the Chinese Hospital and test plates are being taken five days each week. Local physicians are referring patients to the x-ray center, and the epidemiology is being done by public health nurses of the San Francisco Health Department. Chinatown had a tuberculosis mortality rate last year of 138.9 deaths per hundred thousand of population compared to the entire state rate of 48 for the same period.

CONNECTICUT

New Dean of College of Pharmacy.—Harold G. Hewitt, Ph.D., for twenty-one years with the department of chemistry, University of Buffalo, has been appointed dean of the College of Pharmacy at the University of Connecticut, effective July 1. He is president of the Section on Chemistry, American Association of Colleges of Pharmacy.

Society News.—Dr. Creighton Barker, New Haven, executive secretary of the Connecticut State Medical Society and secretary to the Connecticut Medical Examining Board, has been elected president of the Connecticut Cancer Society. Ira V. Hiscock, Sc.D., chairman of the department of public health at Yale University, was elected vice president, and Miss Grace Mooney, executive assistant of the state medical society, secretary.

DISTRICT OF COLUMBIA

University Appointments.—On July 1 Dr. Edward B. Tuohy, Rochester, Minn., became director of the department of anesthesiology at Georgetown University School of Medicine. He is a graduate of the University of Pennsylvania School of Medicine, Philadelphia, 1932, and has been a member of the staff of the Mayo Foundation for many years. He succeeds Dr. Fred R. Sanderson, resigned, who will retire but continue on the staff of the university as clinical professor of surgery. Dr. Robert J. Coffey became professor of surgery July 1. A graduate of Georgetown University School of Medicine, 1932, he has recently been professor of experimental surgery and instructor in clinical surgery at Georgetown.

FLORIDA

Donner Hall at Palm Beach.—The Donner Foundation, Inc., has deeded a $150,000, sixty-four room building in Palm Beach, Fla., to the Institutum Divi Thomae, Cincinnati, for scientific research. The building, to be known as Donner Hall, was formerly a part of the estate of the late Col. E. R. Bradley and is adjacent to the Institutum's Marine Biological Laboratories. Donner Hall will provide quarters for a marine biophysics laboratory for intensive fundamental research in cancer and quarters for visiting scientists from various parts of the world, who will be invited to participate in a series of symposiums devoted to different fields of research. The Institutum Divi Thomae, founded in 1935 by the archbishop of Cincinnati, is a graduate research school with fourteen affiliated units throughout the United States. William H. Donner, 83, a millionaire Philadelphia steel man who has previously given large sums to cancer study, is director of the Donner Foundation.

IDAHO

State Medical Election.—At the annual meeting of the Idaho State Medical Association at Sun Valley, June 19, Drs. Albert B. Pappenhagen, Orofino, became president, Franklin B. Jeppesen, Boise, president-elect and Wallace Bond, Twin Falls, secretary-treasurer. The 1948 annual meeting will be held at Sun Valley.

ILLINOIS

Emergency Water Supply Insured in Case of Disaster.—The first of six water purifiers capable of meeting the emergency needs in case of disaster in Illinois communities has been received by the state department of health from the American Red Cross. The gas engine driven purifiers are capable of purifying 15 gallons of water per minute and are a part of the disaster preparedness operations in Illinois. Purchased from the War Assets Administration by the Red Cross, the purifiers will be located at strategic points throughout the state. The purifiers are familiar to thousands of American soldiers who served overseas in areas where water from ponds and polluted streams had to be purified for drinking and cooking purposes.

Chicago

Illinois Professors to Retire.—The following retirements at the University of Illinois College of Medicine, Chicago, have been announced, effective September 1: William H. Welker, Ph.D., head of the department of biologic chemistry, who has been on the faculty since 1913 and chairman of the committee on graduate study; Dr. Dietrich Klemptner, an associate in medicine, who joined the university faculty in 1928; Dr. Charles Phifer, professor of surgery, who has taught at Illinois since 1913; Dr. Herman L. Kretschmer, professor of urology, and Dr. Kellogg Speed, professor of surgery, who joined the staff in 1941, when Rush Medical College affiliated with the University of Illinois.

Dr. Luckhardt Made a Distinguished Service Professor.—Dr. Arno B. Luckhardt, professor of physiology at the University of Chicago School of Medicine and discoverer of ethylene gas as an anesthetic, has been designated distinguished service professor of physiology at the university. Dr. Luckhardt received his Ph.D. from the University of Chicago, 1911, his M.D. from Rush Medical College, and honorary degrees from Conception College, Conception, Mo., and Northwestern University, Evanston. He was appointed instructor in physiology in 1912, was made a professor in 1923, and has received the Callahan memorial award for accomplishments in medical research. He is a past president of the American Physiological Society and of the Federation of American Societies for Experimental Biology.

MASSACHUSETTS

Public Health Appointments.—The following appointments have been announced by the state department of health, Boston: as epidemiologists, Drs. Victoria M. Cass; Claire F. Ryder, Brooks Ryder and Joseph H. Hanson. Dr. Nicholas J. Fiumara has been promoted to director, division of venereal diseases, pending qualification by civil service.

Helen Putnam Fellowship Award.—Dr. Frances J. Bonner, Boston, was awarded the Helen Putnam Fellowship for advanced research in genetics or in mental health for the second and final year at commencement exercises, Radcliffe College, June 4. Dr. Bonner was the first recipient of this fellowship, which carries a stipend of $2,000 and is open annually to a mature woman scholar qualified to carry on significant research or creative work. She graduated at Boston University School of Medicine, 1943, and is a research fellow in neuropathology at Harvard Medical School. She will continue research which she has been carrying on during the present academic year on the hereditary factors in hysteria.

MISSOURI

Jackson County Installation Banquet.—More than 350 members of the Jackson County Medical Society attended the sixty-fifth annual installation banquet in Kansas City June 26. Dr. Robert L. Hoffman was installed as president. Rev. Thomas McCartan Knapp, S. J., president of Rockhurst College, Kansas City, spoke on "The Soul and the Doctor." Recognition of the centennial year of the American Medical Association was made by the inclusion inside the program cover of four of the special three cent stamps bearing the reproduction of the painting "The Doctor." Two laymen were presented gold keys and citations. Mr. Arthur B. Eisenhower, vice president of the Commerce Trust Company, was cited for his leadership in the Jackson County cancer fund campaign, and Conwell Carlson, reporter for the Kansas City *Star*, was cited for "lifting the curtain on medical news in Kansas City." The society has a membership of 680.

NEBRASKA

State Medical Election.—At the May annual meeting of the Nebraska State Medical Association Dr. George E. Charlton, Norfolk, became president, and Dr. James E. M. Thomson, Lincoln, was made president-elect; Drs. Milton H. Carrig, Bloomfield, and Earle E. Farnsworth, Grand Island, vice presidents; Roy B. Adams, Lincoln, secretary, and Mr. M. C. Smith, Lincoln, executive secretary.

Appoint Head of New County Health Department.—Dr. Corinne S. Eddy is health director for the newly created Lincoln and Lancaster County Health Department. The new unit is an extension of the Lincoln City Health Department, authorized by the legislature to include all Lancaster county citizens. Dr. Eddy received her Ph.D. at the University of Chicago and her medical degree from the University of Illinois College of Medicine, Chicago. She has done public health work in Alabama and Mississippi.

NEW MEXICO

State Medical Election.—At the annual session of the New Mexico Medical Society in May Dr. Victor K. Adams, Raton, became president. Philip L. Travers, Santa Fe, was named president-elect, and H. L. January, Albuquerque, secretary-treasurer.

NEW YORK

Meeting of School Physicians.—New York State's Association of School Physicians and the School Nurse Teachers Association will meet with the Annual Conference of Health Officers and Public Health Nurses at the Grand Union Hotel, Albany, July 28. The presidential address will be given by Dr. Edgar Bieber, Dunkirk. Dr. Francis H. Marx, Oneonta, will speak on "The Wetzel Grid"; Dr. Konrad E. Birkhaug, New York State Department of Health, Albany, on "BCG Vaccination"; Col. Herbert Pollack, New York, "Malnutrition in the Armed Forces and in Concentration Camps and Its Significance in the School Health Program," and Dr. Albert D. Kaiser, health officer, Rochester, "The Spastic Child and the School."

Tristate Medical Meeting.—Chautauqua County Medical Society will sponsor its twelfth annual interstate medical meeting at the Chautauqua Institution grounds at Chautauqua Lake July 24. On the medical program Dr Abraham H. Aaron, moderator, William F. Lipp and Leon J. Leahy, all of Buffalo, and George W. Crile, Cleveland, will participate in a discussion of peptic ulcer. The "Present Status of Thyroid Disease" will be discussed by Dr. Crile and Dr. John H. Talbott, professor of medicine at the University of Buffalo Medical School; and Dr. Paul D. White, Boston, will speak on "Recent Advances in Our Knowledge of Heart Disease." Physicians from western New York, northwestern Pennsylvania and the northeastern corner of Ohio are invited to attend.

New York City

Personal.—Dr. Adolph G. Kammer, Oak Ridge, Tenn., has been appointed director in charge of the medical activities of all plants of Carbide and Carbon Chemicals Corporation and will be located at South Charleston, W. Va. He is a graduate of the University of Pennsylvania School of Medicine, 1928. ——Dr. Burton L. Zohman has been appointed attending physician to the Long Island College Division of Kings County Hospital in Brooklyn and associate professor of clinical medicine at the Long Island College of Medicine.——Dr. Harold A. Abramson, assistant professor of physiology, Columbia University College of Physicians and Surgeons, and associate physician for allergy, Mount Sinai Hospital, has been appointed consulting physician for allergy at the Sea View Hospital, Staten Island.

Dr. Loeb Made Bard Professor of Medicine.—Dr. Robert F. Loeb has been appointed Bard professor of medicine at Columbia University College of Physicians and Surgeons and director of the medical service at Presbyterian Hospital effective July 1, succeeding Dr. Walter W. Palmer, who became emeritus professor and a consultant of the Presbyterian Hospital. Dr. Loeb received his medical degree from Harvard Medical School, Boston, 1919. He has been associated with Presbyterian Hospital for many years and was associate medical director of the Neurological Institute 1938-1941. In 1942 he became Lambert professor of medicine and attending physician at Presbyterian Hospital. During the late war he was a consultant to the Office of Scientific Research and Development and chairman of the Board for the Coordination of Malarial Studies, charged with the responsibility of developing new drugs for the management of malaria. He recently served as chairman of the Board of Review of the United States Atomic Energy Commission. He is chairman of the Fellowship Board of the National Research Council and a past president of the American Society for Clinical Investigation.

OHIO

License Revoked.—Dr. Lloyd L. Jones, Columbus, has been convicted of criminal abortion by the Franklin County Court of Common Pleas, and his certificate to practice medicine was revoked by the board, according to the *Ohio State Medical Journal.*

Personal.—Dr. Thomas A. Gardner, Springfield, assistant public health director of the city since last October, assumed his duties recently as director of health.——Dr. Drew L. Davies, Columbus, has been appointed national chairman of the services on first air, water safety and accident prevention of the American Red Cross.

Hospital News.—Contracts have been recently let for the construction of a 105 bed hospital addition at the Stillwater Sanatorium (District Tuberculosis Hospital) at Dayton, jointly operated by Montgomery and Preble counties. The superintendent of the 107 bed hospital is Dr. Everett F. Conlogue.

UTAH

Appoint Head of Department of Obstetrics and Gynecology.—Dr. Emil G. Holstrom, associate professor in the department of obstetrics and gynecology, has been named professor and head of the department to succeed Dr. Charles E. McLennan, who has accepted an appointment as chairman of the department of obstetrics and gynecology at Stanford University School of Medicine, Stanford University-San Francisco. A graduate of the University of Minnesota Medical School, Minneapolis, 1938, he was a teaching fellow in obstetrics and gynecology at Minnesota University hospitals. He was on the staff of Salt Lake General Hospital, and later an instructor in his field at the University of Minnesota School of Medicine, Minneapolis, 1942-1943, and from there came to the University of Utah School of Medicine as an associate professor.

Cancer Research.—A total of $25,805 has been allocated to the University of Utah School of Medicine, Salt Lake City, by the American Cancer Society in the form of three research grants and one fellowship. This includes $3,000 per annum to be given to Dr. Charles M. Huguley Jr., fellow in medicine under the guidance of Dr. Maxwell M. Wintrobe, professor and head of the department of medicine; $4,560 allotted to Dr. Wintrobe for the study of halogenated amines and related compounds and of irradiation in the management of leukemia, Hodgkin's disease and lymph node diseases, and $10,395 granted to Dr. George Sayers, Ph.D., for work on urinary output and adrenocorticotropin and regulation of pituitary adrenocorticotropic activity. The remainder was granted to support a study by Dr. H. Henry Lerner, professor and head of the department of radiology, on the protective and therapeutic action of roentgen radiation and chemical agents in mice with experimental leukemia and lymphosarcoma.

WISCONSIN

University to Repeat Infantile Paralysis Course.—The University of Wisconsin Medical School, Madison, will repeat the intensive course in the diagnosis and therapy of poliomyelitis July 21-26 at the Medical School and the State of Wisconsin General Hospital as well as the Wisconsin Orthopedic Hospital for Children. Again this course is being presented by the medical school in cooperation with the county chapters of the National Foundation for Infantile Paralysis, Inc., throughout Wisconsin. Thirty-three physicians attended the course during its first offering. Details can be obtained from Dr. Llewellyn R. Cole, Coordinator of Graduate Medical Education, Medical School, University of Wisconsin, 418 North Randall Avenue, Madison 6, Wis.

WYOMING

State Medical Election.—At the meeting of the Wyoming State Medical Society in Sheridan June 23-25 Dr. Emory W. DeKay, Laramie, became president. Dr. George E. Baker, Casper, was named president-elect; Drs. Dewitt Dominick, Cody, vice president; George H. Phelps, Cheyenne, secretary, and Peter M. Schunk, Sheridan, treasurer. Mr. Arthur Abbey of Cheyenne was appointed executive secretary, and Dr. E. Earl Whedon, Sheridan, is the newly appointed editor of the state journal.

PUERTO RICO

Committee Studies Need for Doctors and Nurses.—A joint committee of the Puerto Rico Medical Association and lawmakers is undertaking a comprehensive survey of the needs of doctors and nurses here. All the government agencies and municipalities have been contacted in an effort to recommend measures against the shortage in these professions and to improve medical services. The committee is composed of Drs. Juan A. Pons, health commissioner; A. Oliveras Guerra, Manuel Astol, Jerenfel Cordero, representing the Puerto Rico Medical Association and the department of health, and Senators Vicente Geigel Polanco, Francisco Anselmi and Adolfo Monserrate. A list of all vacancies for doctors in government institutions and municipalities is being prepared as well as a list of all young medical students now studying medicine in continental United States and other countries. The list comprises also all medical students who have graduated through scholarships offered by the University of Puerto Rico and other institutions here as well as data on foreign physicians who are now working for government institutions in the island.

GENERAL

Board of Pathology Examination.—The American Board of Pathology has declared that after Jan. 1, 1948 all applicants for certification will be required to take the examinations of the board. The last meeting of the American Board of Pathology before this date will be October 24-25 in Chicago.

New Society for Study of Arteriosclerosis.—The American Society for the Study of Arteriosclerosis was created in Atlantic City, June 9. Dr. Wilhelm C. Hueper, New York, was elected president, William B. Kountz, St. Louis, vice president, and Dr. Otakar J. Pollak, Wilmington, Del., secretary-treasurer.

Opium Traffic Increases.—Traffic in prepared opium has been rising since 1944, the federal narcotics commissioner, Washington, D. C., said June 7 in his report for 1946. The aggregate weight of seizures at the borders and ports was 22,471 ounces, compared with 9,567 in 1945. Most of the raw opium seized, it was said, originated in Iran.

National Medical Association Meeting.—The fifty-second annual convention of this association will meet at the Jefferson High School, Los Angeles, August 18-22 under the presidency of Dr. Walter A. Younge, St. Louis, as guests of the Southern California Medical, Dental and Pharmaceutical Association. There will be general meetings, section meetings, round table discussions and a program of entertainment. The annual oration in medicine will be given by Dr. William G. Tyson, Savannah, Ga., on "Cryptorchism and Gynecomastia."

New Foundation for Research in Rheumatic Fever.—An announcement was made July 7 of the formation of the Helen Hay Whitney Foundation for basic scientific research in rheumatic fever. The distributing committee of the foundation are Mrs. Charles S. Payson (Joan Whitney), New York; John Hay Whitney, New York; Frederick K. Trask Jr. and William Harding Jackson, New York. Dr. T. Duckett Jones, Boston has been appointed medical director of the foundation with temporary offices in the New York Hospital, 525 East 68th Street, New York. Dr. Jones stated that the purpose of the foundation is to make possible research which may increase our knowledge of rheumatic fever.

Cancer Foundation Names President.—Abbott Kimball, president of Abbott Kimball Company, Inc., New York, on June 3 accepted the presidency of the National Cancer Foundation, Inc., created last May "to press for government action against cancer and to lead other activities seeking care of cancer victims not now handled by an organized group." Mr. Kimball has served as treasurer of the foundation. He succeeds Julius J. Perlmutter. The foundation expects to establish a series of advanced cancer hospitals throughout the United States. The foundation, with headquarters at 85 Franklin Street, New York, has just been granted a charter as a corporation under the laws of the state of New York.

Dr. Eliot on Leave from Children's Bureau.—The United Nations is to conduct a survey of the relief programs being carried out in seven central and eastern European countries by its International Children's Emergency Fund, under the direction of Dr. Ludwig Rajchman, chairman of the board, which operates the emergency fund. Dr. Martha M. Eliot, associate chief, U. S. Children's Bureau, and president-elect of the American Public Health Association, now on leave from the bureau, will be chief medical consultant. A group of four health and medical officers will spend several weeks touring children's institutes and inspecting other facilities. It is expected that the Emergency Fund will help feed 20,000,000 children through the national relief services which have been set up in each country.

Nutrition Awards.—The American Institute of Nutrition made two awards at its annual dinner in Chicago May 19. The Borden award for 1947 was presented to Leonard A. Maynard, Ph.D., Ithaca, N. Y., for contributions to the physiology of milk secretion, factors affecting milk production and milk composition, and the requirements of animals for dietary fats. The Mead Johnson and Company award for research on the vitamin B complex was presented to Dr. William J. Darby, associate professor of biochemistry, Vanderbilt University School of Medicine, Nashville, Tenn., Paul L. Day, Ph.D., professor of physiologic chemistry, University of Arkansas School of Medicine, Little Rock, and E. L. Robert Stokstad, Ph.D., research chemist, Lederle Laboratories, Pearl River, N. Y., for their investigations on B complex vitamins with special reference to studies on the chemistry and nutritional significance of folic acid.

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the periods indicated have been received from the division of public health methods, U. S. Public Health Service:

	Week Ended			Total to		Total *

Medical Women's Library Fund.—The American Medical Women's Association is planning to raise $500,000 to erect a building for the Medical Women's Library, which came into its possession in 1933. The Woman's Medical College of Pennsylvania, Philadelphia, donated the site and will assume responsibility for its upkeep. The collection was presented to the American Medical Women's Association by Dr. Bertha Van Hoosen, Chicago, at the close of the Century of Progress exposition and has been housed in the Quine Library, 1853 Polk Street, Chicago. A trained librarian gives half time service to the supervision and upkeep of files, correspondence, books, manuscripts, press notices and other details. The library collects articles or information by or about women in science and maintains up to date information concerning women physicians and material memorializing pioneer women of science. It functions through a committee. Annual or life memberships may be secured for $10 and $100, respectively, book memberships for $2 or Sadler Memorial Memberships for $1. Checks may be made to Dr. Bertha Van Hoosen, Chairman, American Medical Women's Association, 25 East Washington Street, Chicago.

Foreign Group to Study American Blood Program.—Scholarships for the study of blood and its derivatives have been offered to a selected group from foreign countries by the American Red Cross in cooperation with the League of Red Cross Societies. The candidates will be proposed by the national Red Cross societies and will be selected on a basis of personal and professional qualifications as well as on the need in their country for information on the use of blood fractions. The scholarships will be for nine to twelve months of study in the United States and will have a value of $2,500-$3,000. The training will include study of method of recruiting donors, collecting and processing blood, processing plasma and the uses of blood and blood derivatives in medicine and public health. Field work will be done in North Dakota for mobile field laboratory operation, in Michigan for its state plan of plasma fractionation and in Miami, Fla., for private blood bank maintenance. Details of the training were worked out by Dr. Warren F. Draper, Washington, D. C., assistant administrator, Medical Services, American Red Cross, in cooperation with Dr. Charles A. Janeway of Boston, chairman of the Red Cross Advisory Committee on Blood and Blood Derivatives.

Appoint Epidemic Coordinator.—The National Foundation for Infantile Paralysis, 120 Broadway, New York, has created an office of epidemic coordinator to insure maximum efficiency in meeting the challenge of poliomyelitis this summer. All epidemic activities of the national office will be channeled through the office of Epidemic Coordinator West J. Altenburg. He will be assisted by a committee: Dr. Hart E. Van Riper, Scarsdale, N. Y., medical director; Louis H. Haughey, comptroller, and George H. LaPorte, director of public relations. The epidemic coordinator's responsibility will be the speedy recognition of danger spots, correlation of information and of national office and field activities, and the evaluation of requests from the field to avoid duplication of effort. Equipment pools, each with respirators and hot pack machines, have been established by the foundation in Boston, Columbus, Ohio, and Des Moines, Iowa. Four epidemic aid teams, each consisting of an epidemiologist, orthopedist, pediatrician, an orthopedic nurse and two physical therapists, are ready to go into any epidemic area at the request of state health departments. The foundation reports that the country is better equipped to cope with infantile paralysis outbreaks than ever before and that cooperation between official and private agencies, state and county health departments, general hospitals, medical and nursing groups and the National Foundation has been improved.

International College of Surgeons.—The twelfth annual assembly and convocation of the United States chapter of the International College of Surgeons will meet September 28-October 4 at the Palmer House, Chicago, under the presidency of Dr. Herbert A. Acuff, Knoxville, Tenn. A combined operative and clinical program has been arranged. Besides numerous authorities, members of the United States chapter, the following visitors will be on the program: Dr. Hamilton Bailey, London, England; Dr. Raymond Darget, Bordeaux, France, "Treatment of Inveterate Cystitis by Infiltration of the Nervi Erigentes and Denervation of the Bladder"; Dr. Basil Hughes, Cornwall, England, "Lister's Conceptions and Those of Today"; Dr. William O. Lodge, Halifax, England, "Transantral Approach to the Gasserian Ganglion"; Dr. Felix Mandl, Jerusalem, Palestine, "Sympathetic Block in Sympathetic Surgery"; Dr. J. Almeida Rios, Rio de Janeiro, "Surgical Treatment of Osteomyelitis"; Dr. August Maria Sisson, Porto Alegre, Brazil, "New Technic to Produce Better Apical Collapse of the Lung"; Dr. Alex W. Spain, Dublin, Ireland, "Symphysiotomy in Modern Obstetrics."

On October 3 operative clinics, round table discussions and demonstrations will be held at Cook County Hospital under the direction of Dr. Karl A. Meyer, and clinics will be given October 4 at many Chicago hospitals. Dedication of the home of the United States chapter of the International College of Surgeons, the Blair mansion, 1516 Lake Shore Drive, purchased earlier this year, will take place at 8 p. m. October 2. The annual banquet will be held at the Palmer House at 6 o'clock October 1, and convocation will be at the Stevens Hotel, October 3, at 8 p. m. Reservations should be made promptly by writing Dr. Francis D. Wolfe, Chairman, Housing Committee, International College of Surgeons, % Chicago Convention Bureau, 33 North LaSalle Street, Chicago 2.

FOREIGN

Bubonic Plague in Haifa.—Palestine Senior Medical Officer Dr. James S. M. Pollock reported July 7 that bubonic plague had stricken 14 persons at Haifa. Antiplague measures launched by health authorities include a widespread rat extermination campaign, the spraying of infected areas with DDT and warnings to the population to take certain preventive measures.

Acta Urologica.—A new periodical under this title aims to publish special articles in the field of surgical urology and allied fields of medical science. It is a joint publication of the Clinic for Surgical Urology of the Pazmany Peter University of Budapest and the Publishing Company of the Free Union of the Hungarian Physicians and Surgeons. It will be published in English, French, Russian and German and will appear six times a year. The editors are A. Babics and E. Szold of Budapest, and on the board of collaborators are names from Vienna, Paris, Bern, Prague, Bratislava, Bucharest and Copenhagen.

CORRECTION

Postgraduate Courses for Practicing Physicians.—In the June 21 issue of THE JOURNAL, page 734, the second institution and course listed should read American College of Radiology, 20 North Wacker Drive, Chicago; at various cities during the year; radiology; one week; $50.

Marriages

GEORGE LEONARD EMMEL III, Gainesville, Fla., to Miss Rachel Bushnell Rodenbach of Naugatuck, Conn., March 29.

EVERT ALFRED LARSSON, Trenton, N. J., to Miss Torborg Margareta Eriksson in Lidköping, Sweden, February 9.

FRANCIS LEO MCNELIS, Pawtucket, R. I., to Miss Shirley Lucille Grube at Pocantico Hills, N. Y., June 21.

EUGENE B. MELINKOFF, Los Angeles, to Miss Beryl Cameron of San Francisco in Las Vegas, Nev., recently.

JOHN WESTON MANDEVILLE, Muskegon, Mich., to Miss Marilyn Ann Thomas of Detroit March 22.

LOGAN OLIVER JONES, Charlotte, N. C., to Miss Joan Duncan Shaw of Greenwich, Conn., March 15.

ALFRED E. GREENWALD, New York, to Miss Leatrice Joy Fleishman at Newark, N. J., June 15.

JOHN LEWIS READ, Camden, N. J., to Miss Dorothy Patricia Diana of Sharpsville, Pa., February 8.

JOHN C. MARKLEY, Georgetown, Ohio, to Miss Eleanore Dundon at Cincinnati February 15.

EDWIN S. OLSAN, Rochester, N. Y., to Miss Dorothy R. Dryfoos of New York January 23.

JOSEPH MARKEL, Staten Island, N. Y., to Miss Barbara Klauber of New York March 14.

JOHN EUGENE RAY to Miss Jane Rooks Tuttle, both of Humboldt, Tenn., Dec. 30, 1946.

VINCENZO R. ONORATO, Montclair, N. J., to Miss Ida Di Bella of Verona in February.

ROBERT HUGH MANHEIMER to Miss May Rosner, both of New York, March 2.

JACK H. LEVY, Newington, Conn., to Miss Beatrice Bogin at Hartford March 15.

WOODROW MILLER to Miss Joyce Lee Davidson, both of Los Angeles, recently.

Deaths

Thomas Martin Joyce ⊕ Portland, Ore.; born in Emmetsburg, Iowa, Jan. 28, 1885; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1910; an intern and surgical assistant at St. Mary's Hospital, Rochester, Minn.; during World War I chief surgeon at Base Hospital number 46, serving with the American Expeditionary Forces; Kenneth A. J. Mackenzie professor of surgery and head of the department at the University of Oregon Medical School; chairman, Section on Surgery of the American Medical Association, 1939-1940; member of the founders group of the American Board of Surgery; formerly vice president of the American Association for the study of Goiter and the Pacific Coast Surgical Association; member of the American Surgical Association, Portland Academy of Medicine, Southern Surgical Association, North Pacific Surgical Association and the American Association for the Study of Trauma; fellow of the American College of Surgeons; attending surgeon at St. Vincent's Hospital; head of the department of surgery at the Portland Clinic and the Multnomah County Hospital, where he died April 18, aged 62, of coronary thrombosis.

Oscar Theodore Schultz, Evanston, Ill.; Johns Hopkins University School of Medicine, Baltimore, 1903; past president of the Illinois Society of Pathologists; member of the American Association of Pathologists and Bacteriologists; specialist certified by the American Board of Pathology; veteran of the Spanish-American War and World War I; for many years on the staff of the Michael Reese Hospital in Chicago and St. Francis Hospital; died in the Veterans Administration hospital March 7, aged 69, of acute cholangitis, miliary liver abscesses and old hemiplegia.

Virginia Pereira Alvarez-Hussey, Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1920; died in the Woman's Hospital April 12, aged 56, of malignant hypertension and cardiac decompensation.

Frank Leroy Andrews ⊕ Chicago; Chicago College of Medicine and Surgery, 1916; on the staff of the Grant Hospital; died April 19, aged 61, of cerebral hemorrhage.

Harold Taylor Antrim ⊕ Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1917; served during World War I, as city police surgeon and on the staffs of the Episcopal Hospital and Stetson Hospital, where he died April 28, aged 54, of hemorrhage due to esophageal varices and portal cirrhosis.

Harry N. Azar ⊕ Wheeling, W. Va.; Georgetown University School of Medicine, Washington, D. C., 1928; killed in an airplane accident near Moundsville April 20, aged 47.

Louise W. Beamis-Hood ⊕ Buffalo; University of Buffalo School of Medicine, 1919; for many years secretary of the Medical Society of the County of Erie; served as president of the Women's Medical Society of the State of New York and as vice president of the Medical Women's National Association; died in the Buffalo General Hospital April 12, aged 68, of hypertension and myocardial infarction.

Robert L. Bean, Cleveland, Tenn.; Chattanooga Medical College, 1898; served on the county draft board during World War I; died April 19, aged 80, of myocarditis.

Jacob Andrew Bieri Jr., St. Louis; St. Louis University School of Medicine, 1930; member of the American Medical Association; formerly on the faculty of his alma mater; died in the Alexian Brothers Hospital April 12, aged 41, of cirrhosis of the liver and rheumatic heart disease.

Enos Hoyt Bigelow, Framingham, Mass.; Harvard Medical School, Boston, 1882; member of the American Medical Association; past president of the Massachusetts Medical Society and the Middlesex South District Medical Society; served in the state legislature; chairman of the board of health and the school committee; on the staff of Framingham Hospital; died March 13, aged 91, of arteriosclerosis.

Joseph Emanuel Blasenstein, New York; Columbia University College of Physicians and Surgeons, New York, 1920; specialist certified by the American Board of Pediatrics; for many years affiliated with the contagious disease division of the city health department; member of the staffs of the Sydenham and Morrisania hospitals; died April 3, aged 50, of coronary thrombosis.

Alta Emma Cullen Bordner, Duncan Okla.; Northwestern University Woman's Medical School, Chicago, 1892; for many years affiliated with the Colorado State Hospital in Pueblo, Colo.; died in the Lindley Hospital April 2, aged 72, of coronary thrombosis.

Joseph G. Bosley, Richmond, Ky.; University of Louisville Medical Department, 1892; served as county health officer; director of the Richmond Building and Loan Association; on the staffs of the Pattie A. Clay Infirmary and the Gibson Hospital where he died April 7, aged 79, following an operation for Hirschsprung disease.

Thomas McGrath Brennock ⊕ Jersey City, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1917; past president and secretary of the Hudson County Medical Society; fellow of the American College of Surgeons; diagnostician for the city board of health; served during World War I; affiliated with the Margaret Hague Hospital, Greenville Hospital, Fairmont Hospital and the Medical Center, where he was chief of the gynecologic service and where he died April 3, aged 55, of carcinoma of the bladder.

Alcus James Carter, Dayton, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1911; served as president of the Jones County (Miss.) Medical Society; formerly superintendent of the South Mississippi Charity Hospital, Laurel; died April 17, aged 64, of cerebral hemorrhage.

Crawford Haralson Cleveland ⊕ Anniston, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1915; on the staff of the Anniston Memorial Hospital; president of the Y. M. C. A. board of directors; director of the Anniston Chamber of Commerce and the Commercial National Bank; died in Emory Hospital, Atlanta, April 2, aged 58, of glioblastoma.

Elmer Sherman Clouting ⊕ Philadelphia; Jefferson Medical College of Philadelphia, 1896; affiliated with the Philadelphia General Hospital for many years; died in the Chestnut Hill Hospital April 29, aged 75, of nephritis and edema of the lungs.

John Andrew Collins ⊕ Washington, D. C.; Washington University School of Medicine, St. Louis, 1902; fellow of the American College of Surgeons; member of the staff of the Episcopal Eye, Ear and Throat Hospital; died April 9, aged 69, of pulmonary edema.

Sidney James Colton ⊕ Johnstown, N. Y.; University and Bellevue Hospital Medical College, New York, 1909; for many years public school physician; served on the staff of the Nathan Littauer Hospital in Gloversville; died April 8, aged 62, of coronary occlusion.

Percy Ray Cruse, Houston, Texas; Memphis (Tenn.) Hospital Medical College, 1912; member of the American Medical Association; chief consulting surgeon for the Burlington-Rock Island Railroad; died March 28, aged 59, of cerebral hemorrhage.

Hiram Day, Maryville, Mo; Ensworth Medical College, St. Joseph, 1892; served as county physician and as deputy state health commissioner; on the staff of St. Francis Hospital; died April 11, aged 78, of coronary sclerosis.

Frank K. Doane, St. Louis; St. Louis College of Physicians and Surgeons, 1905; served on the staffs of the Christian and St. John's hospitals; died April 27, aged 65, of heart disease.

John Donnelly, Charlotte, N. C.; University of North Carolina School of Medicine, 1905; member of the American Medical Association and the American College of Chest Physicians; past president of the Southern Sanatorium Association; served in France during World War I; formerly superintendent of the Mecklenburg Sanatorium in Huntersville; died April 9, aged 68, of cerebral hemorrhage.

Charles John Edwards, Vicksburg, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1907; member of the American Medical Association and the American Academy of Ophthalmology and Otolaryngology; served during World War I; on the staff of the Vicksburg Hospital, Mercy Hospital and Vicksburg Infirmary; died March 13, aged 62, of coronary thrombosis, arteriosclerotic heart disease and chronic nephritis.

James Washington Ethridge, Lucy, Tenn.; University of Tennessee Medical Department, Nashville, 1899; served on the staffs of the Methodist, John Gaston, Baptist and St. Joseph's hospitals in Memphis; died April 14, aged 73, of heart disease.

Charles Israel Granstein, Chicopee, Mass.; Tufts College Medical School, Boston, 1910; died in the Mercy Hospital, Springfield, April 11, aged 59, of angina pectoris.

Leopold Sanford Gumberts ⊕ Chicago; Jenner Medical College, Chicago, 1908; died April 27, aged 83, of chronic myocarditis.

Alpheus Tisdale Hafford ⊕ Albion, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1913; fellow of the American College of Surgeons; city health officer; on the staff of the Sheldon Memorial Hospital; died in Battle Creek April 23, aged 57, of coronary thrombosis.

Emory Sylvester Hall ⊕ McLeansboro, Ill.; Northwestern University Medical School, Chicago, 1908; served overseas during World War I; captain, medical reserve corps, not on active duty; owner of the McLeansboro Hospital; died April 4, aged 73, of coronary thrombosis.

Harold Charles Harpfer ⊕ Wheeling, W. Va.; University of Pennsylvania School of Medicine, Philadelphia, 1926; member of the medical staffs of the Ohio Valley General and the Wheeling hospitals; died April 1, aged 46, of coronary thrombosis.

Eric Albert Hartley ⊕ Chicago; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, Germany, 1913; associated with the Columbus Hospital; served an internship and residency at the Knickerbocker Hospital in New York and the American Hospital in Chicago, where he died April 10, aged 59, of carcinoma.

William Davis Hawker, St. Louis; St. Louis University School of Medicine, 1911; member of the American Medical Association; died in the Deaconess Hospital April 3, aged 73, of septicemia.

Major Joel Henderson, Baker, Fla.; Rush Medical College, Chicago, 1937; died April 1, aged 38, of rheumatoid arthritis.

William Clarence Hess ⊕ Cresco, Iowa; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901; president of the Howard County Medical Society; president of the staff of the Mercy Hospital; died April 6, aged 72, of heart disease.

John Thomas Hickerson, Kansas City, Mo.; Marion-Sims College of Medicine, St. Louis, 1892; served during World War I; died March 10, aged 80.

William A. Hillemeyer ⊕ Chicago; Jefferson Medical College of Philadelphia, 1896; member of the staff of the Woodlawn Hospital; died April 5, aged 71, of coronary occlusion.

James Arthur Holley, Walton, N. Y.; Albany Medical College, 1886; member of the American Medical Association; died April 20, aged 92, of heart disease.

Irving Woodward Hollingshead ⊕ Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1894; on the staff of the Methodist Hospital, where he died April 23, aged 75, of pneumonia.

Harwood Leroy Hollis ⊕ Lacona, N. Y.; Syracuse University College of Medicine, 1920; past president of the Oswego County Medical Society; fellow of the American College of Chest Physicians and the American Trudeau Society; member of the village board; formerly a member of the board of education of Sandy Creek High School; served as president of the First National Bank of Lacona; superintendent of the Oswego County Sanatorium in Richland; died April 28, aged 52, of coronary thrombosis.

Thomas Jefferson Houston, Meridian, Miss.; University of Tennessee Medical Department, Nashville, 1889; served during World War I; formerly city health officer; at one time on the faculty of the Mississippi Medical College; died April 18, aged 81.

George Stem Hulick, Aldan, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1943; member of the American Medical Association; interned at the Hahnemann Hospital; served during World War II; was accidentally shot and killed March 29, aged 30, while cleaning a pistol.

William Otis Hunt, North Falmouth, Mass.; Harvard Medical School, Boston, 1877; member of the American Medical Association; for many years on the staff of the Newton (Mass.) Hospital; died in Wiscasset, Maine, April 19, aged 92, of cerebral hemorrhage.

Adolph Xavier Kamm, Ashland, Wis.; the Hahnemann Medical College and Hospital, Chicago, 1918; member of the American Medical Association; on the staff of St. Joseph's Hospital; died March 30, aged 57, of coronary occlusion.

Herbert Weaver Kendell ⊕ Covington, Ohio; Ohio Medical University, Columbus, 1898; for many years member of the board of education, director and president of the Covington Building and Loan Company; served on the staff of the Piqua (Ohio) Memorial Hospital; died March 16, aged 71, of cerebral hemorrhage.

Harriet Ann Knott, Saginaw, Mich.; New York Medical College and Hospital for Women, Homeopathic, New York, 1894; died in Midland March 17, aged 79, of pneumonia.

George Abraham Lassman ⊕ New York; College of Physicians and Surgeons, Baltimore, 1906; member of the American College of Chest Physicians; died April 3, aged 63, of heart disease.

Isidor Morris Lavine ⊕ Mount Rainier, Md.; George Washington University School of Medicine, Washington, D. C., 1941; also a lawyer; diplomate of the National Board of Medical Examiners; interned at the Gallinger Municipal Hospital in Washington, D. C.; affiliated with the Prince Georges' General Hospital, Cheverly, where he was secretary of the staff; on the staffs of the Sibley and Children's hospitals in Washington, D. C.; died April 5, aged 42, of coronary occlusion.

Edward McCrady L'Engle, Jacksonville, Fla.; Johns Hopkins University School of Medicine, Baltimore, 1902; served as secretary-treasurer of the Florida Public Health Association; for many years director of the bureau of vital statistics and formerly member of the state board of health; for many years trustee of the city public library and president of the board of directors of St. Luke's Hospital; died April 19, aged 68, of cerebral hemorrhage.

Isaac Richard Le Sage, Huntington, W. Va.; Medical College of Ohio, Cincinnati, 1888; died April 30, aged 81.

Frank Liberson, New York; Long Island College Hospital, Brooklyn, 1917; specialist certified by the American Board of Radiology; member of the American College of Radiology; served with the U. S. Public Health Service; roentgenologist at the radiologic clinic at U. S. Marine Hospital number 13 on Staten Island; died April 16, aged 58, of coronary occlusion.

Walter Lineback, La Belle, Fla.; Cincinnati College of Medicine and Surgery, 1897; died March 27, aged 79, of acute dilatation of the heart.

Walter M. McGaughey ⊕ Greencastle, Ind.; Medical College of Indiana, Indianapolis, 1902; county and city health officer; veteran of the Spanish-American War; surgeon for the New York Central and Pennsylvania Railroad; died March 24, aged 75, of coronary disease.

John Malcolm Maples, Florence, Ala.; University of Louisville (Ky.) School of Medicine, 1907; member of the American Medical Association; died in Selma March 21, aged 74, of coronary thrombosis.

Milton Leon Mooney, Mountain Home, Ark.; College of Physicians and Surgeons, Little Rock, 1907; served as health officer of Baxter County; died April 1, aged 70, of cerebral hemorrhage.

Howard Delano Moore, Danbury, Conn.; Hahnemann Medical College and Hospital of Philadelphia, 1893; member of the American Medical Association; served on the staff of the Danbury Hospital; died March 28, aged 79, of gangrene of the foot, diabetes mellitus and general arteriosclerosis.

Carroll Hampton Morgan, Memphis, Tenn.; Chattanooga Medical College, 1910; member of the American Medical Association; died in the Baptist Hospital March 29, aged 60 of cerebral hemorrhage.

Joseph Nack, Kew Gardens, N. Y.; University and Bellevue Hospital Medical College, New York, 1911; served on the staff of the Harlem Hospital in New York; died in February, aged 57.

Andrew Nagy, West Los Angeles, Calif.; Magyar Királyi Pázmány Petrus Tudományegyetem Orvosi Fakultasa, Budapest, Hungary, 1927; died in Santa Monica March 1, aged 46, of myocardial infarction and arteriosclerosis.

Lorenzo Bowen Phillips ⊕ Inwood, N. Y.; University of Pennsylvania Department of Medicine, Philadelphia, 1895; for many years affiliated with St. Joseph's Hospital in Far Rockaway; died March 31, aged 82, of coronary thrombosis.

Elbridge Worthington Pierce, Meriden, Conn.; University of the City of New York Medical Department, New York, 1885; president emeritus of the Meriden Hospital; died April 4, aged 84, of arteriosclerotic heart disease.

Joseph Pore ⊕ Ambridge, Pa.; Maryland Medical College, Baltimore, 1911; also a pharmacist; member of the American Heart Association; examining physician, Beaver County Local Board number 6, Selective Service System; medical examiner for the local school system; served on the staffs of St. Elizabeth Hospital in Youngstown, Ohio, and the Sewickley Valley (Pa.) Hospital; died in the Mercy Hospital, Pittsburgh, April 27, aged 64, of carcinoma of the lung.

George Thomas Pruitt, Meridian, Miss.; Memphis (Tenn.) Hospital Medical College, 1912; died March 20, aged 73, of coronary thrombosis.

George William Pugsley ⊕ Bayard, Neb.; John A. Creighton Medical College, Omaha, 1907; an officer in the medical corps of the U. S. Army during World War I; for many years councilor of the Twelfth District of the Nebraska State Medical Association; died March 23, aged 66, following an automobile accident.

Thomas Everette Romine, Charleston, W. Va.; University of Louisvile (Ky.) School of Medicine, 1911; died March 28, aged 60, of a skull fracture received when struck by an automobile.

Benjamin Clark Sawyer, Darlington, Pa.; Medical Department of the Western University of Pennsylvania, Pittsburgh, 1903; member of the board of education; died March 2, aged 70, of cardiovascular renal disease.

Richard Frederick Schiele ⊕ Glen Ellyn, Ill.; University of Illinois College of Medicine, Chicago, 1915; died April 9, aged 55.

George Winthrop Shoemaker, Syracuse, N. Y.; Syracuse University College of Medicine, 1897; one of the founders of the Onondaga General and People's hospitals; died March 29, aged 84, of myocarditis.

Shelby Epler Stinnette ⊕ St. Paul; the Hahnemann Medical College and Hospital, Chicago, 1913; affiliated with Midway, Mounds Park and Bethesda hospitals; died in Los Angeles March 27, aged 60, of coronary thrombosis and hypertension.

Fred Foster Stocking, Fargo, N. D.; Rush Medical College, Chicago, 1906; member of the American Medical Association and the Minnesota State Medical Association; fellow of the American College of Surgeons; served overseas during World War I; chief rating officer at the Veterans Hospital; died in April, aged 67.

Lieut. (jg) Ford P. Eshleman Jr.
(MC), U. S. N. R., 1919-1945

Capt. Ralph C. Berkelhamer
M. C., A. U. S., 1914-1944

Capt. John S. Doherty
M. C., A. U. S., 1914-1945

Henry Edward Stone, Boston; Tufts College Medical School, Boston, 1912; member of the American Medical Association; interned at the Lynn (Mass.) Hospital; died in Miami Beach, Fla., March 31, aged 57, of coronary thrombosis.

Frank Austin Teepell, Russell, N. Y.; University and Bellevue Hospital Medical College, New York, 1899; member of the American Medical Association; served as health officer; died recently aged 76.

William Scott Tinney Sr., Strasburg, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1903; member of the American Medical Association; served as coroner and physician for the board of health; died March 21, aged 67, of angina pectoris.

Karl Rand Tuttle, Haverhill, Mass.; Dartmouth Medical School, Hanover, N. H., 1888; died March 28, aged 86, of myocarditis and arteriosclerosis.

Pitt Abraham Wade, Canon City, Colo.; Barnes Medical College, St. Louis, in 1898 and 1899; died in National City, Calif., March 19, aged 77, of carcinoma of the prostate.

Jacob R. Wiggers, Grand Rapids, Mich.; Ohio State University College of Homeopathic Medicine, Columbus, 1917; member of the American Medical Association; died March 22, aged 61, of coronary thrombosis.

Thomas Marion Williams, Palo Alto, Calif.; Columbia University College of Physicians and Surgeons, New York, 1901; served in the U. S. Navy during World War I; formerly member of the city council; served as health officer of Palo Alto, medical adviser for Stanford University and special consultant in surgery at the Men's Student Health Service; for many years chairman of the Stanford Board of Athletic Control; affiliated with the Palo Alto Hospital; died March 26, aged 76, of cerebral hemorrhage.

KILLED IN ACTION

Ford Powell Eshleman Jr., Lakemills, Wis.; Northwestern University Medical School, Chicago, 1943; interned at the St. Luke's Hospital in Chicago, where he served a residency; began active duty in the medical corps of the U. S. Naval Reserve as a lieutenant (jg) on Oct. 10, 1944; began sea duty as ship's surgeon on the U. S. S. *Napa* which landed Fourth Division Marines on Iwo Jima on D-Day; aboard the U. S. S. *Braine* which was on patrol duty from Leyte to Okinawa and was attacked by enemy suicide planes off the east coast of Okinawa on May 27, 1945, aged 26; declared dead Oct. 5, 1945.

Ralph Carl Berkelhamer, Chicago; University of Illinois College of Medicine, Chicago, 1939; interned at the Englewood Hospital and the Cook County Hospital, where he served a residency; began active duty as a first lieutenant in the medical corps, Army of the United States, in May 1941; promoted to captain; prisoner on Bataan, where he survived the "Death March"; detachment commander at the hospital unit at Prison Camp Number 1 at Cabanatuan; awarded Silver Star for gallantry in action on Bataan and Bronze Star for excellent service while in prison camp; killed in action in the South China Sea Oct. 24, 1944, aged 30, when the ship on which he was being transported was sunk.

John Stephen Doherty, Lockport, N. Y.; University of Buffalo School of Medicine, 1941; diplomate of the National Board of Medical Examiners; interned at the Buffalo Hospital of the Sisters of Charity; began active duty as a first lieutenant in the medical corps, Army of the United States, on Aug. 18, 1942; promoted to captain; battalion surgeon of the 319th Glider Field Artillery; missing in action in Holland on Sept. 18, 1944; declared dead Sept. 19, 1945 by the War Department, aged 31.

Alleged Injury to Workers at an Atomic Research Station

It is alleged that workers in an atomic research center in England have developed symptoms arising from their employment. This claim is made in the daily press by the assistant general secretary of the Chemical Workers Union. Among the symptoms enumerated are lassitude, skin eruptions and impotence. Of 250 men working at the plant he states that 20 complain of impotence. This allegation is being investigated by the inspectors of the Ministry of Labor. At the same time a spokesman of the Ministry of Supply has stated that the only instance of disorder due to radioactivity in this and other plants is 1 case of dermatitis. Also Professor N. F. Mott, president of the Atomic Scientists Association, has stated that the methods of protection are so easily applied and so strictly enforced that it is inconceivable that workers could be affected. The impotence and sterility of which radar workers complained during the war were apparently not of occupational origin. It has to be remembered that, with a labor government in control of the country, workers have every opportunity to exploit real or alleged grievances.

Army Memorial to Help the Living

The Royal Army Medical Corps War Memorial Fund, for which $36,000 has been raised within the corps itself, has been commended to a wider public by Lieut. Gen. Sir Alexander Hood, director general of the army medical services. It is proposed to spend the fund mainly for the living rather than set up an expensive monument. This decision was taken by a large meeting representative of all ranks and all types of service. The fund will therefore be devoted first to the welfare of families of all ranks of the corps who fell in the war; also of all ranks who served in the war, and of their families, who may be in need through sickness or other misfortune. The intention is not to build up any large capital sum but to give substantial help where necessary. It is expected that the fund will be all distributed in some six or seven years.

At a press reception held at the headquarters of the corps Sir Alexander Hood made a threefold appeal for support of the fund: to his comrades of all ranks of the corps, to physicians in civil life, and to other arms and services and the general public. He felt that among the many thousands who passed, sick or wounded, through the medical units there were many who would like to take this opportunity of paying a practical tribute to those who looked after them in desert, jungle, prison camp, and every theater of war.

Artificial Insemination: Moral and Legal Objections

It is only recently that the question of artificial human insemination has attracted attention in this country. A conference on the subject has been held in London under the auspices of the Public Morality Council. The subject was discussed from every point of view by speakers representing the medical profession, the churches and the law. The problem was outlined by Dr. H. P. Newsholme, health officer of Birmingham. In the artificial insemination of a wife with her husband's semen he objected to obtaining the semen by masturbation as a lowering of human dignity. The only legitimate method was insemination from the vaginal pool after normal coitus. Mr. Kenneth Walker, a neurologist, who is an expert in male fertility, dealt with the use of donated semen. He had seen many more marriages saved rather than wrecked by this procedure. The theological aspect was dealt with by speakers representing the Roman Catholic Church, the Church of England and the Free Churches. Rev. J. C. Heenan, D.D., speaking for the Roman Catholic Church, condemned artificial birth prevention as "masturbation *à deux* and morally wrong. It was not only permissible but extremely desirable that marital intercourse, for some reason unfruitful, should be perfected by medical skill. This might take the form of preparing the vagina beforehand in order to overcome some obstacle or intervention after normal intercourse to assist the deposited seed toward its natural objective. But artificial fecundation properly so called was unlawful. Artificial insemination from a donor was revolting. For the Church of England Rev. G. L. Russell, a physician also, said that for insemination of a wife there was no practical alternative to masturbation and he did not believe that on moral grounds this should be prohibited. But, like all the clerical speakers, he regarded the use of donor's semen as morally objectionable.

A lawyer, Mr. J. P. Ashworth, saw great legal difficulties in the use of donor semen. If pregnancy followed and the mother registered the child as her husband's she would be guilty of perjury. Also the child would be illegitimate. Legacies to the child in the belief that it was legitimate would be invalidated. Then there was the danger that children of the same father, ignorant of the fact, might marry and so be guilty of incest.

The case for artificial insemination was stated by two women doctors. Dr. Mary Barton said that artificial insemination had been a portion of her daily practice for five years. About 10 per cent of marriages were sterile, and in about 60 per cent of these the male was affected. In about 3 per cent he was hopelessly sterile. There was no greater disruptive element in married life than a fertile woman living with a man who could never give her a child. There was no stronger urge in the developed woman than the bearing of children. Adoption of children was a solution in only a minority of cases. In arranging for a donor of semen it was insisted that the matter should remain a secret. Appalling damage might be done to the child by the discovery that the man reputed to be its father was actually not. In an experience of 300 donor cases the results had been satisfactory. The children were healthy and the woman and her husband had been happy.

Paraplegia Following Spinal Anesthesia: Damages for Negligence Against the Hospital Authorities

The disastrous effect of a spinal anesthetic has led to legal proceedings in which heavy damages for negligence were awarded against the hospital authorities but not against the medical staff responsible for the operation—a most unusual difference in such cases. A boy fractured his femur while playing football and was taken to a hospital at Portsmouth. In order to reduce the fracture a spinal injection of nupercaine was given in the ward, not in the operating room. Some days later meningitis was diagnosed, which was found to be due to infection with Pseudomonas aeruginosa. The result was that the boy became permanently paraplegic and could not retain his urine. In the action for damages three members of the medical staff of the hospital, including the orthopedic surgeon, were cited as defendants with the hospital authority. The judge found no evidence of any negligence on their part in the treatment of the fracture, the decision to administer a spinal anesthetic, the doing so in the ward instead of the operating room, or in treating the patient after the meningitis was diagnosed. He was satisfied that the skin was properly cleansed before the operation and that the operator had prepared himself in the approved way. The only remaining source of infection was the apparatus, for which the nursing staff was responsible. The infection could not have arisen without negligence on the part of the hospital service. He accordingly gave judgment in favor of the medical staff but against the hospital authorities. For the terrible disability of the boy, for which no money could compensate, he awarded $48,000 damages with costs. Notice of appeal against this judgment was lodged.

Outbreak of Bubonic Plague

In March and April this year an outbreak of bubonic plague, of which Turkey had been free for a number of years, was reported from the southern frontiers of Urfa, where it was confined to three villages. The Ministry of Health immediately rushed by airplane the necessary equipment for preventive and curative measures to the infected areas. The frontiers were immediately closed and put under strict quarantine. The whole population of all southern provinces was vaccinated. All means of transportation were inspected and disinfected. Day and night almost two hundred persons (the director general of hygiene, 1 specialist, 1 bacteriologist, 1 district health officer, 68 health officers and physicians, 75 sanitary inspectors and 53 sanitary agents) were engaged in the work and two mobile hospitals and one mobile laboratory were used for the destruction of rats, mice, vermin and insects. Five and one-half tons of DDT, 201 tons of gasoline and 191 tons of benzine were employed. There have been 18 cases and 13 deaths and on April 9 the outbreak was considered closed. It has been revealed that the disease came in from Syria, where it is sometimes sporadic among desert nomads along the frontier and where no serious attempts had been made to prevent its spread. In the infected frontier villages only a few dead rats were found infected with Bacillus pestis.

The vigil along the frontier has not been abandoned, especially as recently 6 new cases of bubonic plague have been reported from the Syrian village of Varta. All arrivals from Syria must submit to close examination. The Central Institute of Health has provided the southern provinces with a generous supply of vaccine and serum. The outbreak has been reported in full detail to the Interim Commission of the World Health Organization at Geneva.

The Shortage of Trained Nurses

In 1942 the Turkish Red Crescent Society in Istanbul opened the first nursing school in Turkey. An eighth grade school certificate was required for admission to the competitive entrance examination. No fees were charged for tuition, board, maintenance and uniforms. The course was three years and a diploma was given. After graduation a five years compulsory service was required, and marriage during this period was not permitted. Noncompliance obligated the student to repay the expenses incurred in her training. At its inception the school had many applications and had from thirty to forty graduates each year. Most of the theoretical instruction was given by physicians and foreign trained nurses; for practical experience the students were sent to government and city hospitals. Graduates were given positions at governmental general hospitals. After several years of satisfactory work these nurses advanced to the position of head nurse.

With the advent of the republic, the reorganization of hospitals and the extension of health activities, it became increasingly evident that the number of graduates from this one school was wholly inadequate to meet the demand, especially as since the beginning of the last war the number of applications decreased and students began to leave after the probationary period. Less than a hundred students have graduated from the school so far. Bedside nursing at nearly all hospitals is still mostly done by practical nurses, who after a certain time and if their work has been satisfactory take an examination; having satisfied the board of examiners, they receive a certificate and an increase in pay, but they never attain the status of a trained nurse. In male wards and dermatologic clinics male nurses are employed. At present the place of the trained nurse in many general and maternity hospitals is taken by the trained midwife, of which there is no shortage.

There are at present four schools of nursing in Turkey. One, the Red Crescent School of nursing in Istanbul, with an enrolment of almost a hundred students and under the direction of two American trained nurses, and the two schools of nursing established last year in Istanbul by the Ministry of Health, one in affiliation with the Haydar Pasha Model Hospital, the other in affiliation with the Children's Hospital and an enrolment of almost a hundred students. In addition to free tuition, board, maintenance and uniforms, the students receive a monthly allowance of 30 liras a month. Theoretical instruction is given by the medical staff of the respective hospitals. The graduates are required to give five years of compulsory service at governmental hospitals for expenses incurred in their training. At the head of these schools are two Turkish trained nurses who had several years of postgraduate work and study in the United States. The funds for the administration of these schools come from the budget of the Ministry of Health. To procure trained nurses for army hospitals the Army School of Nursing, with an enrolment of almost a hundred students, was opened at the beginning of the war at the Gulhane Military Hospital in Ankara. The requirements for admission and the educational program are the same as in the other schools, but in addition to a small allowance the students receive officer's food rations, but the obligatory service is ten years instead of five. The Turkish Child Welfare Society of Ankara has a foundling home with three hundred inmates, to which is attached a school for the training of children's nurses. The course is two years and the graduates are given positions at the many branch homes the society has in all parts of the country.

Last September the cornerstone was laid at Ankara for a 200 bed Red Crescent hospital in affiliation with a second Red Crescent School of Nursing for 200 students. The plans for the hospital and school were drafted by the French architect Jean Walter, who has also prepared the plans for the medical center now under construction in Ankara. The Red Crescent Hospital and School are expected to be finished by the end of next year.

There are also plans for the systematic training of male nurses. The number of trained nurses in Turkey is at present 457; of practical nurses, 631.

The inadequate supply of trained nurses for hospital and public health work will probably continue to be a problem for some time. The emancipation of women must also be regarded as a contributing factor to the shortage. Most girls with a higher education now enter professions that were formerly not open to them, and the continually growing school population also demands more and more teachers for all grades. To attract more desirable candidates to the nursing profession a law was passed in 1945 according to which trained nurses in government service who had already attained civil servant status in 1926 were promoted to a higher salary class. Under the 1945 law they are eligible for a pension.

School of Hygiene Renews Courses

With twenty physicians from different provinces, the School of Hygiene at Ankara, which in 1941 discontinued courses on account of war conditions, has recently renewed courses. Health officers, physicians engaged in antimalarial work and physicians engaged in work at health centers are taking a four months theoretical and practical course in preventive medicine, epidemiology, vital statistics, general, social, industrial and rural hygiene, microbiology, malaria control work and sanitary engineering. The instructors are specialists from the Ministry of Health and Social Assistance and from Rockefeller fellows who did graduate work in preventive medicine in the United States. Field work is being done at the Etimesut Health Center, the Central Institute of Hygiene, the Ankara Model Hospital and the Malaria Prevention Center. For the small number of participants and the short duration of the course, postwar conditions and the continuing mobilization are responsible. It is hoped that a course of longer duration with more participants from remote provinces may be given next fall. The present course aims to prepare physicians so they will be able to direct the health centers that are to be opened in the near future.

Protection of the Liver and the Kidneys

Dr. Carlo Foa, professor at the University of Milan, Italy, has published his experimental studies performed at the Institute of Physiology of São Paulo, where he is a guest professor, on the protection of the liver and the kidneys by the synergic action of disintoxicating and lipotropic factors. The aim of Dr. Foa's studies was to compare the lipotropic power of choline with that of an enzymatic proteolysate of casein containing methionine, the antihepatosteatosis factors extracted from the pancreas, and the lipotropic and antinecrotic factors from an integral proteolysate of liver. He studied the separate action of each factor and also the simultaneous interaction of all of them.

As a fundamental alipotropic diet Dr. Foa used what he called diet A, containing casein 5 per cent, peanut flour 20 per cent, lard 20 per cent, starch 20 per cent, saccharose 28 per cent, agar 2 per cent, yeast 2 per cent, cod liver oil 2 per cent and Hawk and Oser's salt mixture 1 per cent. Rats fed on diet A showed a slow increase in weight and an extensive loss of hair, particularly of the head and sides. Several of these animals died on about the sixtieth day of the experiment from hepatic and renal disturbances caused by the diet. The postmortem examination of the liver disclosed steatosis with a variable distribution of fat. The most striking changes were present in the cells bordering the acinus near the periportal conjunctive tissue. Fat was seldom found in the central part of the lobuli but frequently in the intermediate zone. In some animals the most important changes were found around the central vein; in some others the fatty degeneration was mostly in the intermediate zone of the acinus, while its central part showed only necrobiotic lesions. A third group of animals presented fatty degeneration of the central part associated with severe necrosis of the intermediate zone. In many cases these diverse pictures were simultaneously found in different zones of the liver of the same animal, with fatty infiltration of the periphery of the acinus besides zones of necrosis and fatty degeneration of the central part. The infiltrated zones always presented the phenomenon of birefringence, the lipids, free or included in Kupffer's cells, being as a rule anisotropic. In some cases also the crystalline formations presented the anisotropic condition. Some rats were also fed on diets called B, C and D, the first containing 20 mg. of choline per day, the second containing the same amount of choline plus 20 mg. of inositol per day and the third one containing 20 mg. of choline and 20 mg. of the antihepatosteatosis factor extracted by the method proposed by Entenman, Montgomery and Chaikoff.

The average weight percentage of lipids of the liver of a lot of 10 rats fed on diet A was 22.65, while the same average for similar lots of animals fed on diets B, C and D was respectively only 9.70, 7.22 and 4.80. These results, in coincidence with the findings of microscopic examinations, demonstrated that the improvement caused by the lipotropic factors under study is more extensive when they act synergically, with great influence on the increase in weight, the growth of hair and the lipid content of the liver. Dr. Foa's conclusion is that choline, fed to rats showing definite liver steatosis caused by alipotropic diets without methionine, presents a high lipotropic power, which is increased by the synergic action of inositol. The action of these two factors is still greater when potentiated by the addition of the antihepatoesteatosis factor of Entenman, Montgomery and Chaikoff.

Chemistry of Normal Blood of Adults

Drs. Mario P. de Mesquita and Vera L. Ribeiro of the Fernandes Figueira Hospital of Rio de Janeiro have been studying for a number of years the blood chemistry of normal adults. Several of their studies have been reported in previous letters (hemoglobin, calcium, urea). The same authors have now published a report of their investigations on the normal content of uric acid in the blood, including 201 determinations; 152 in male persons and 49 in female persons. The variation of the value in males was minimum 1.6 mg., maximum 5.1 mg., mean 3.44 mg., standard deviation 0.61 mg.; in females minimum 1.6 mg., maximum 4.4 mg., mean 2.83 mg., standard deviation 0.65 mg. The mean value for the 152 males is 3.5 practically identical in all age groups.

The Antireticular Cytotoxic Serum

Drs. Eimar Povoa and Walter Guerreiro have reported the results of their first experimental work on the effects of the Bogomolets antireticular cytotoxic serum. After two years of hard work they succeeded in preparing the antireticular human serum, using spleen and bone marrow taken from a man free from infection and from cancer a few hours after his death. Using a technic similar to that of the preparation of rabbit serum against guinea pig and sheep serum against rabbit, they obtained a serum of low hemolytic power and with a high titer, which was employed in several human cases with partially good results. The present paper is a preliminary report.

Death of Dr. R. Leitão da Cunha

Dr. R. Leitão da Cunha, president emeritus of the Rio de Janeiro University, died recently at the age of 67. Graduating in 1902 from the Rio de Janeiro Medical School, Dr. Leitão da Cunha studied for some time in Europe. Returning to Brazil he was appointed professor of pathology at the Rio de Janeiro University and some time later was chosen to be president of the university. During a few years he was commissioner of health for the Federal District. He published several textbooks of medicine, among which was one on clinical pathology, which had a large use in Brazil. Two years ago he retired from active service, receiving the title of president emeritus of the university.

Brief Items

Dr. Arnaldo de Moraes, professor of clinical gynecology, University of Rio de Janeiro, has been elected corresponding member of the Société française de gynécologie. At the same time Dr. Moraes has been invited to be present at the eleventh French Congress of Gynecology, to be held this month at Chatel Guyon, France.

Dr. Amadeu Fialho, pathologist of the National Department of Health, has been appointed professor of pathology at the University of Rio de Janeiro, succeeding Dr. Paul Leitão da Cunha, who died a few weeks ago. Dr. Fialho, a leading specialist, is well known throughout the country. He is the author of many valuable papers.

Dr. C. Goulart de Andrade has been elected president of the Brazilian Association of Obstetrics and Gynecology. Dr. Andrade is assistant professor of obstetrics at the University of Rio de Janeiro.

Correspondence

THE THYROID GLAND

To the Editor —I had the good fortune many years ago to be able to point out the dominating role of the thyroid gland in the production of energy To the present day I am still surprised at the favorable reception which that research received and to find from time to time my name mentioned along with others to whom, in my opinion, science is indebted for the truly great discoveries in endocrinology Those men had a creative insight and imagination for the solution of their problems involving the discovery of new resources and methods, both chemical and surgical Nothing like this was requisite for my task The problem presented itself to me almost of its own accord Friedrich Mueller (*Deutsches Arch f klin Med* **51**:335, 1893) was the first, in 1892, to draw attention to the altered protein metabolism in hyperthyroidism Thereupon Leichtenstern and Murray (*Deutsche med Wchnschr*, 1894, No 50) independently in 1893 inferred from purely clinical observation that the loss of weight resulting in obese patients from thyroid feeding must be due in part to combustion of their accumulated fat and thus yield an increased energy production At that time I carried Mering and Zuntz respiration apparatus to the bedside of the patient There was nothing more to do than to examine the gaseous metabolism in hyperthyroidism and in myxedema (Magnus-Levy, Adolph *Berl klin Wchnschr*, 1895, No 30, *Ztschr f klin Med*, 1897, Nos 3/4), a task which was accomplished in less than three years

Fifty years have elapsed, and only now do I believe myself in a position to interpret the favorable reception accorded to these studies Their success may have depended on the great simplicity of the question as formulated, as well as on the method employed for its answer In addition it may be due to the circumstance that the problem was solved once and for all exclusively within the domain of human pathology

I desire to express my deep felt gratitude to my American friends, who chiefly because of it invited me to New Haven and provided me, a stranger in a strange land, with a sheltering roof for the pursuits of my old age

Adolph Magnus Levy, M D, New York

RHEUMATIC PNEUMONITIS

To the Editor —Dr G C Griffith in his article on "Rheumatic Fever" (The Journal, April 5, p 974) appears to consider that rheumatic pneumonitis was first described in 1927 This is not so, for I referred to it in my 'Manual of Children's Diseases" which was first published in 1905 One review severely criticized my statements, but since then I find that this type of pneumonia is now well recognized both in Great Britain and in America Let me quote my original reference to it "It may be also that pneumonia may occasionally be caused by the specific organism of rheumatism" I agree with Dr Griffith that subcutaneous nodules are not necessarily a grave prognostic sign I stated in my book that I had "on several occasions met with rheumatic nodules where the patient was not very seriously affected and made a rapid and good recovery" Again, I state that "appendicitis is undoubtedly a rheumatic affection in not a few cases" I consider it a mistake to give sodium bicarbonate along with sodium salicylate or acetylsalicylic acid As a rule too the doses given are inadequate In cases of acute rheumatism doses much beyond the average are well tolerated and yield better results

James Burnet, M D,
14, Cumin Place,
Edinburgh, 9, Scotland

CANCER TREATMENT BY AUTOVACCINATION

To the Editor —In the correspondence on "Cancer Treatment by Autovaccination" in The Journal, March 15 and May 10, no mention is made of the significant work by Thomas Lumsden between the years 1925 and 1936 The fundamental work is reviewed in the *American Journal of Cancer* **15**:563, 1931, the most recent paper in the series is in the same journal **32**:395, 1938

Since 1929, when Woglom published his somewhat overcritical review of tumor immunity (*Cancer Res* **4**:129, 1929) the scientific atmosphere has been hostile to the subject of tumor immunity, and possibly valuable experimental work has been rejected on insufficient evidence Lumsden's experiment on autovaccination in the treatment of transplanted tumors was apparently conclusive In one especially significant experiment he studied a large group of animals which had sarcomas implanted on both hind legs By injecting repeated small doses of formaldehyde into one tumor in each rat he was able to bring about a slow regression of the injected tumor In a very large percentage of the treated animals the uninjected tumor also regressed so that both tumors were ultimately entirely destroyed A comparison with control uninjected tumor bearing animals showed that the result was significantly due to the treatment employed In subsequent work Lumsden carried out a careful analysis of the mechanism of this phenomenon and showed that it involved an autoimmunization with the formation of cytotoxic antitumor antibodies

This important critical and imaginative research seems to have been overlooked by most investigators in the field

Arthur Shapiro, M D, Brooklyn

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Governmental Hospital: Right of City Hospital to Remove Physician from Regular Staff.—The plaintiff filed suit to enjoin the defendant city from suspending him from the staff of a hospital which it operates. From an order denying an injunction, the plaintiff appealed to the Supreme Court of Florida.

Regulations governing the operation of the municipal hospital of Lakeland were approved by the city in 1943. Among other things, these regulations provided that "(A) The regular staff shall consist of those physicians, surgeons and dentists practicing in the city of Lakeland who have been, or may be, appointed by the Staff Executive Committee as hereinafter provided, and whose memberships have been approved by the City Commissioners." In relation to suspension of members of the staff, the regulations provided that "(19) Dismissal from Membership. Suspension. Members of the staff may be recommended for suspension or dismissal for unprofessional conduct or for the violation of the rules of the staff or of the hospital. Charges against staff members must be in writing to the president of the staff, who will refer the matter to the executive committee for investigation and recommendations, after which a vote of the staff shall be taken without discussion. A two thirds majority vote by secret ballot shall be necessary for the suspension or dismissal of the staff member. All staff members must be notified in writing of such contemplated action at least two weeks prior to the time of taking vote." The executive committee referred to in paragraph 19 consists of five members of the regular staff elected at the annual meeting each year. It serves for a period of one year, and to it is designated the duty to investigate any complaints that arise pertaining to the efficiency of the hospital or to irregularities of staff members. The plaintiff applied for membership on the regular staff in 1944, his application stating (in accordance with the approved form) "I agree to abide by the rules and regulations of the medical staff as approved by the city commission. I also agree to keep accurate and up to date records of patients under my care and complete their records within seventy-two hours after discharge of patient. I also agree to attend 75 per cent of the meetings of the staff." The permit issued to the plaintiff and approved by the city commission contained substantially the same provisions. On Nov. 1, 1945 the city manager issued the following directions: "To all staff members: Please be advised that beginning on the above date the supervisor of each floor has been instructed not to permit any patient to be taken to surgery unless the following is recorded on the patient's chart: 1. A complete physical examination. 2. Preoperative diagnosis. 3. Laboratory report. Also on all cases of therapeutic abortion there must be recorded two consultations with other physicians, one of which must be an obstetrician. This matter was brought up for discussion at a meeting of the executive committee of the medical staff held Oct. 31, 1945 and motions made, seconded and carried that the above ruling be enforced."

On Jan. 16, 1946 the superintendent of the hospital notified the plaintiff of a meeting of the executive committee on that day and urged the plaintiff to attend, which he did. The meeting was concerning the plaintiff and his noncompliance with the hospital regulations. The executive committee met again on February 12, and the plaintiff was invited to attend that meeting but he did not do so. On March 8 the committee held another meeting to which plaintiff was invited. He did not attend, stating that the committee could do as it pleased. On March 12 formal charges were given the plaintiff, and the executive committee granted him seventy-two hours in which to answer the charges and set March 15 as the day for further hearing. At the March 12 meeting, however, the committee made a formal report of charges but explained to the plaintiff that, although notice to the staff for a meeting on March 26 had been sent out, the executive committee would gladly hear any explanation which he wished to make. The plaintiff did not attend the meeting scheduled for March 15. On March 26, after the required two weeks notice, the staff voted to recommend to the city commissioners, and did recommend the next day, the indefinite suspension of the plaintiff from the staff for repeated unprofessional conduct. On April 4 the city commission met for the purpose of determining whether or not to suspend the plaintiff from the staff of the hospital. The plaintiff had been notified of this meeting and requested to attend. He was represented instead by his attorney, who read a letter which informed the city commission that the plaintiff had filed suit to secure such relief as it was possible for the court to allow under the law but asked for no action by the city commission. After the letter had been read, the attorneys were asked if they had any further statement to make. They had nothing more to say and left the meeting. The city commissioners then approved the recommendations of the staff and suspended the plaintiff.

The Supreme Court said that it was not incumbent on the city to maintain a hospital for the private practice of medicine and that a physician does not have a constitutional or statutory right to practice his profession in the city's hospital. It is well recognized, the court continued, that reasonable rules and regulations may be prescribed concerning the qualifications of physicians permitted to practice in public hospitals and follows that reasonable rules and regulations may also be imposed on physicians regulating their practice within the hospital. The management of the affairs of the city's hospital was in the exercise of a proprietary or corporate capacity as distinguished from one governmental in nature. Even though the hospital be a public hospital, plaintiff as a physician had no right (per se) to practice in the hospital, it being a privilege rather than a right. The court admitted that the city commission has no right to exercise its power in an unreasonable, arbitrary and capricious manner without being subject to judicial review but concluded that in the case presented such behavior was not made to appear. Accordingly the order of the trial court denying plaintiff's injunction was affirmed.—*Bryant v. City of Lakeland, 28 So. (2d) 106 (Fla., 1946).*

Medical Motion Pictures

FILM REVIEW

Manual Rotation in the Management of Occiput Posterior and Occiput Transverse Positions. Directed by H. J. Holloway, M.D., and E. S. Burge, M.D. Produced in 1943 by the Department of Obstetrics and Gynecology, Northwestern University Medical School and the Evanston Hospital. Photography by Mervin W. LaRue. 16 mm., color, silent, 1,100 feet (one reel). Showing time thirty-two minutes. Procurable by rental, $4, or by sale from Audio-Visual Medical Education Department, Northwestern University Medical School, 303 East Chicago Avenue, Chicago 11.

This is a teaching film intended for medical students and others interested in obstetric problems. Position diagnosis, manual rotation of occiput to an anterior position, forceps application and extraction for each of the posterior and transverse positions are explained and clearly illustrated. These technics are demonstrated in detailed steps, first on a "manikin" and then on a patient during an actual delivery. Many other details incidental to delivery are well illustrated, including constant observation of fetal heart tones, correlation of physical findings elicited by vaginal or rectal and abdominal examination, bladder emptying immediately prior to delivery, making of an episiotomy, and inspection and repair of the cervix after delivery.

The authors stress three requirements for successful accomplishment of the maneuver described: (1) accurate diagnosis of position, station and dilatation, (2) good muscular relaxation (they use drop ether anesthesia) and (3) a competent obstetrician. The photography is excellent, while the printed titles do not seem to furnish adequate explanatory remarks, this may have been intentional so that each instructor using this film for a class of students might supply his own narrative.

The film is recommended for showing to students or others interested in obstetric problems. It displays clearly many basic obstetric principles as well as the special maneuver described by the authors.

two weeks in the hospital prior to the thoracolumbar sympathectomy in order that the effects of rest and of the sodium amytal test on the diastolic pressure might be studied. No progression of retinal lesions was observed after sympathectomy in 82 patients with benign essential hypertension. Regression of the retinal hemorrhages, exudates and edema were observed after sympathectomy in 22 of 60 patients in whom hypertension was associated with moderate fundic lesions, but the arteriolar sclerosis remained unchanged in 48. Retinal angiospasm was relieved in 12 patients. Cases of benign essential hypertension showing normal eyegrounds or mild or moderate fundic lesions are suitable for sympathectomy if continued medical treatment is of no avail in alleviating the severe and persisting subjective symptoms. The group of patients who had so-called malignant (rapidly progressive) hypertension with extensive fundic lesions was too small to lead to any conclusion. The chief purpose of sympathectomy is the relief of subjective symptoms in patients with essential hypertension.

Clinical Aspects of Rheumatic Fever in Adults.—Eliaser observed that hemolytic streptococcic infections, including scarlet fever, are common precursors of the acute disease in the adult and are followed by a two to three week period during which extremely strenuous physical activities do not produce symptoms. Clinically significant cardiac murmurs were audible in 45 per cent of the patients at the onset of the disease. Probable valvulitis was revealed in 15 per cent at the onset but was not detectable following convalescence. The involvement of joints among adult patients developing their initial attack in the Pacific Coast area is relatively mild compared to that described in children in several other parts of the United States. The duration of the active phase of the disease averaged sixty-three days.

Adult Rheumatic Fever and Rheumatoid Arthritis.—Engleman says that experience during the last war has stressed the difficulty of differentiating between adult rheumatic fever and rheumatoid arthritis. A comparative study was made of 252 soldiers with active rheumatic fever with carditis and 33 soldiers with acute, "atypical" rheumatoid arthritis. Carditis, when present, usually indicates rheumatic fever, although not necessarily so. The arthritis of atypical rheumatoid disease is apt to be progressive and not migratory, while in adult rheumatic fever it may be either progressive or migratory. The progression of the arthritis may be slower in rheumatoid disease than in rheumatic fever. Unlike rheumatic fever, the antecedent upper respiratory infection is infrequent in rheumatoid arthritis, and when it does occur the latent period is usually shorter. The ineffectiveness of salicylates characterizes rheumatoid arthritis. In rheumatic fever the objective joint improvement is dramatic with the proper administration of salicylates. Erythema, purpura and signs of pulmonary or pleural involvement should favor the diagnosis of rheumatic fever. The elevated sedimentation rate of rheumatoid arthritis continues for a prolonged period, while in most cases of rheumatic fever it is of comparatively short duration.

Plague, Rocky Mountain Spotted Fever and Tularemia in Canada.—Humphreys and Campbell present the results of an eight year survey on the plague, Rocky Mountain spotted fever, and tularemia in western Canada. Plague infection (*Pasteurella pestis*) is prevalent in ground squirrels in a large area of southeastern Alberta and in the adjoining territory of Saskatchewan. Six of 817 tissue pools and 32 of 939 flea pools submitted from 12,676 ground squirrels collected in Alberta, and 2 of 356 flea pools obtained from 7,448 ground squirrels in Saskatchewan proved positive. The infectious agent of Rocky Mountain spotted fever (*Rickettsia dermacentroxenus*) occurs in ticks in both British Columbia and Alberta. Evidence of the infection was found in 5 specimens out of a total of 72,227 ticks collected in British Columbia and in 10 out of 49,201 collected in Alberta. *Pasteurella tularensis* was encountered a total of thirty-eight times in the examination of specimens —ground squirrels, rabbits, mice, certain birds and ticks—submitted from various localities for evidence of plague and Rocky Mountain spotted fever.

Lymphadenopathy in Thiouracil Therapy.—Macht and Herschfus state that a survey of approximately 7,000 cases of thyrotoxicosis in which thiouracil has been employed indicates that toxic reactions occur in about 14 per cent. Lymphadenopathy as a complication was observed in relatively few cases. In a woman aged 67 lymphadenopathy had a dramatic onset eleven weeks after the treatment with thiouracil had begun. The lymph node enlargement was greater than any heretofore reported. The absence of any abnormal lymphocytes in the blood smears and the normal heterophile agglutination precluded the diagnosis of infectious mononucleosis. A malignant lymphoma was ruled out by the rapid progression of the nodes and the inflammatory nature of the reaction. Oral sepsis in the absence of agranulocytosis has been reported as a complication of thiouracil therapy, and this patient's buccal ulcers may have been caused in the same manner. The subsidence of the lymphadenopathy on withdrawal of thiouracil and the lack of other known etiologic factors suggest that the enlargement was a direct result of thiouracil.

*Physical Fitness and Work Capacity of Older Men. E. Simonson. —p, 110.

Nutritional Aspects of Aging.—*Rafsky and Newman* say that there is evidence that in apparently normal aged persons there is a tendency to low blood levels and excretions of thiamine, low blood levels and high tolerance to ascorbic acid, a high incidence of porphyrinuria which disappears on the oral administration of nicotinic acid, and subnormal levels of carotene and vitamin A. Suggested as factors in explanation for these vitamin deficiencies have been inadequate intake of food, lack of vitamins in the diet, insufficient absorption of vitamins by the intestinal tract and failure of the organism to store vitamins. The authors describe investigations of these factors and stress that vitamin requirements of normal elderly people cannot be measured in terms of standards applicable to young adults or children. The diets of old people must be supplemented by vitamin therapy. Comparatively large amounts of vitamin supplement should be prescribed. Clinical experience has shown that at times it is essential to give these vitamins parenterally at the outset and then follow with vitamin therapy by mouth.

Physical Fitness and Work Capacity of Older Men.—Simonson thinks that if employment of older people does not more or less parallel the age shift, serious socioeconomic consequences will result. This raises the question whether increase of life expectancy is associated with a better maintenance of working capacity. If it is, an extension of the period of employment is feasible without important change in work. If, however, extension of the life expectancy is not paralleled by a similar age extension of working capacity, industrial jobs must be adapted to the working capacity of older men in order to maintain their employment. The second important question is whether the various physiologic, biochemical and psychologic functions deteriorate with age at the same rate. The third fundamental problem concerns the possibility of counteracting or delaying the decrease in working capacity with age. The author reviews the information available on these three fundamental problems and shows that much additional information is needed.

Electronic Warning Device for Oxygen Breathing Systems.—Tobias and Siri describe an electronic warning system for use in aircraft equipped with oxygen demand or pressure breathing systems. The device functions on the respiratory rate and is designed to indicate at a central warning panel any interruption in the respiratory cycle greater than fifteen seconds for all oxygen stations. The principle of operation is a time delay circuit which actuates the warning lights on the indicator panel. Operation of the system has proved satisfactory in both laboratory and flight tests.

Sulfadiazine Resistant Streptococcic Infections.—Johnson and Hartman point out that during a program of mass chemoprophylaxis of streptococcic infections in the armed forces it was observed that the effectiveness of such a regimen was lost with the appearance of sulfonamide resistant strains of hemolytic streptococci. While these resistant strains spread in the U S Army and Navy, there had been no reports about epidemics in the civilian population due to sulfonamide resistant strains. Early in 1946 a small epidemic of scarlet fever occurred in Cooperstown, N. Y. Since the first 8 patients with scarlet fever were found to harbor type 19 hemolytic streptococci in their nasopharynxes, it was decided to determine whether they were sulfonamide resistant strains. All eight strains of hemolytic streptococci were found to be resistant to the action of sodium sulfadiazine in a concentration of 25 mg. per hundred cubic centimeters. From Feb 15 to May 1, 1946 streptococcic infections were moderately prevalent in Cooperstown. A table lists the type distribution and sulfadiazine resistance of group A hemolytic streptococci obtained from 100 patients with scarlet fever, pharyngitis, otitis media, wound infections, blood stream infections and pneumonia. The most common streptococcus was type 3, which was responsible for 28 cases of hemolytic streptococcic infections Type 19 was the cause of 24 cases of disease, with 23 of these strains being resistant to sodium sulfadiazine. None of these cases presented special therapeutic problems, nor were they clinically different from infections due to other types of hemolytic streptococci The appearance of increasing numbers of bacteria which are resistant to various chemotherapeutic agents formerly effective against them suggests the desirability of a careful bacteriologic diagnosis of infectious agents prior to treatment with specific antibacterial drugs

Resection of Greater Superficial Petrosal Nerve in Unilateral Headache.—Gardner and his associates present evidence which indicates that periodic discharges of parasympathetic impulses over the greater superficial petrosal branch of the seventh nerve cause unilateral lacrimation, unilateral swelling and secretion of the nasal mucosa and unilateral head pain Since these were the predominating symptoms in 3 cases observed by the authors within a short time, a diagnosis of "greater superficial petrosal neuralgia" appeared justified In 1 of the 3 patients interruption of the nerve was resorted to in order to relieve the attacks After listing seven methods by which attempts have been made to relieve neuralgias of the head, the authors say that in reviewing their own cases they found that since 1938 the greater superficial petrosal nerve has been divided 31 times in 26 patients for the relief of unilateral head pain Most of these patients were benefited, some were not The complications of the operation such as temporary facial paralysis and keratitis are discussed The authors conclude that the operation provides a useful tool in the study and treatment of headache

Dermatome Hypalgesia with Herniation of Cervical Disk.—Keegan says that the clinical syndrome of nerve root compression by posterolateral herniation of a lower cervical intervertebral disk has been well presented in recent articles by a number of observers They have demonstrated that pain which extends from the lower cervical spine over the upper scapula and down the arm, often with associated numb sensation in some part of the hand, commonly is caused by lower cervical disk herniation In the past this syndrome has been variously diagnosed as brachial neuritis, radiculitis, fibrositis, myalgia or reflex pain, with focal infection, cervical arthritis, acromial bursitis, cervical rib, scalenus anticus, cardiac or gallbladder disease often suspected in the etiology. Now it is necessary to reevaluate this type of pain and recognize that it more often is due to nerve root compression by herniation of a lower cervical intervertebral disk. Keegan stresses that the clinical syndrome of lower cervical disk herniation should be recognized as a fairly common cause of pain extending from the lower part of the neck over the scapula and down the arm with numbness of one or more digits of the hand. Unilateral herniation of a cervical disk compresses only one nerve root and gives rise to detectable sensory and motor loss in the distribution of that root. Reduction of pain sensation or hypalgesia from single nerve root loss can be demonstrated by the technic of light pin scratch. Dermatome hypalgesia has been found in 51 clinical cases with history indicative of compression of a lower cervical nerve root by herniation of an intervertebral disk, presenting a new primary dermatome pattern for each of the fourth, fifth, sixth, seventh and eighth cervical nerve roots. Eight clinical cases of cervical rib or scalenus anticus muscle compression of the lower primary cord of the brachial plexus are presented to illustrate the distribution of the anterior primary division of the first thoracic and eighth cervical nerve roots, thus presenting a new diagnostic finding for this syndrome. A distinguishing symptom of lower cervical nerve root compression by herniation of an intervertebral disk is pain over the upper medial scapular region associated with neck movement. The presence of subjective and objective numbness or hypalgesia in an extremity is evidence of an organic lesion of a nerve to the extremity and cannot be classified as reflex pain. Nerve roots, determined by dermatome hypalgesia distributions, maintain a constant position; their location in relation to herniation of an intervertebral disk is more reliable than pathologic change in disks shown by x-ray examination or spinograms. A new dermatome chart of the human body is presented.

Meat and Peas as Source of Protein for Growth.—Lehrer and his associates point out that in low cost diets or when meats are difficult to obtain a common dietary recommendation is an increased use of legumes to meet the protein requirement. Cooked pork, lamb, beef and peas and some combinations of peas and the meats were compared with whole egg as sources of protein for growth in young rats. Measured by growth rate and by efficiency the various meats, when fed at a 10 per cent protein level, were as good sources of protein for growth as were eggs. Cooked peas alone were a poor source of protein for growth. When peas were supplemented with 0.3 per cent dl-methionine, growth was increased until it was not significantly different from that obtained with whole egg protein, although it was not as efficient. At the levels of meat fed in combination with peas, growth was improved over that from peas alone, but even the meat and pea diets were inadequate, as evidenced by a characteristic liver involvement and early death of many of the test animals.

*Maternal Pulmonary Embolism by Amniotic Fluid: Report of a Case. I. I. Goodof.—p. 101.

Maternal Pulmonary Embolism by Amniotic Fluid.—Goodof's patient, a woman aged 40, had had six previous normal deliveries. This time labor began seven hours after rupture of the membranes and terminated in spontaneous delivery of a dead baby, apparently strangled by the cord. Two hours following delivery the patient began to cough and wheeze. Cyanosis developed and was not relieved by oxygen, morphine and atropine. Respiration became more difficult, and the patient died. At necropsy the lungs were found to be wet. Numerous blocks of lung were fixed for sections. The pulmonary arterioles were massively distended with plugs of epithelial squamae, mucus, meconium and numerous polymorphonuclear leukocytes and lymphocytes. The appearance was identical with that seen in the sediment from amniotic fluid. Goodof thinks that embolism of amniotic fluid explains some cases of unexpected postpartum death. He cites reports by Steiner and Lushbaugh in 1941 of cases of pulmonary embolism by amniotic fluid.

Acute Yellow Atrophy Following Cinchophen Administration.—Lenzner and his associates observed the development of acute yellow atrophy in a woman aged 59 the day after the ingestion of 2 Gm. of cinchophen; she died twelve days later. The gross and microscopic findings in the liver differed in some respects from those reported in cases of acute or fulminating hepatitis. Clinical and pathologic evidence of preexisting hepatic disease was absent. There was urinary suppression and early phosphorus retention. In addition to the usual picture of cholemic nephrosis the kidneys showed considerable amounts of calcium within the collecting tubules and their peripheral branchings. The authors point out that the first case of acute yellow atrophy allegedly due to cinchophen was reported about twenty years ago and, although similar cases have been recognized since that time, clinicians who use cinchophen with no observed untoward effects have minimized it as a hepatotoxic agent.

Leukemia Cutis.—In the case reported by Robey and Russell the intense skin involvement began early; the leonine appearance of the face and general leukemic infiltration of the skin led to the diagnosis of leukemia cutis—a rare manifestation, only 4 cases having been seen at the Boston City Hospital in twenty years. Two biopsies early in the disease showed the leukemic lymphocytic infiltration of the lesions. Treatment with navital (fish liver oils) and roentgen radiation having proved ineffective, it was decided to try estrogenic substance, first progynon B, with the addition of diethylstilbestrol later. Under this treatment the symptoms diminished, to increase again when the endocrine therapy was interrupted. The patient, a man aged 51, died suddenly with symptoms that suggested pulmonary embolus. Microscopic examination of the skin showed that the corium was extensively infiltrated by lymphocytes, a typical leukemia reaction. The remainder of the picture was consistent with lymphatic leukemia.

Effect of Topically Applied Sodium Fluoride on Dental Caries.—Knutson and his associates present data on the incidence of dental caries in the permanent teeth of three groups of Rochester, Minn., school children who received two, four and six applications respectively of 2 per cent sodium fluoride solution to the teeth in half the mouth. The incidence of initial caries in permanent teeth which were noncarious at the time of treatment was 9.3, 20.1 and 21.3 per cent less in teeth treated with two, four and six applications of fluoride solution respectively than in untreated teeth. The numbers of additional permanent tooth surfaces which became carious in teeth which were carious at the time of treatment were 16.2, 9.6 and 22.2 per cent less in fluoride treated carious teeth given two, four and six applications respectively than in untreated carious teeth.

DDT in Control of Murine Typhus.—Davis describes the results of an experimental program in San Antonio designed to reduce the number of cases of typhus by controlling the fleas on rats. Previous experiments had shown that the application of DDT to rat runs, burrows and harborages reduces the number of fleas found on the rats. It remained to determine whether the number of cases of typhus can be diminished by dusting DDT in buildings of cities or towns. In the experimental area 20 cases occurred between May 21, 1944 and April 4, 1945, when dusting began. After the program started, 4 cases occurred in treated premises and 10 cases occurred in premises not yet treated. The author concludes that the reduction of rat fleas by distribution of DDT is an additional method for the control of typhus.

Response of Prostatic Cancer to Hormone Therapy.—Deming applied hormone treatment by giving diethylstilbestrol orally, by castration or by a combination of castration and diethylstilbestrol. Synthetic estrogen therapy is of equal and perhaps of more value than castration. When the primary and distant metastatic lesions respond they do so regardless of the method of hormonal application. Dosage of estrogen should be determined on the basis of symptoms, rectal findings, x-ray evidence of osteoplastic activity and acid phosphatase readings. It is just as judicious to apply hormonal therapy early for prostatic cancer as it is to apply any other form of cancer therapy early for other forms of cancer. Synthetic estrogen treatment should be continued as long as the patient lives, whether castration has been done or not. The only known cure for cancer of the prostate is early radical prostatectomy, before it has become a biologic cancer and disseminated to periprostatic and distant organs.

Narcosynthesis.—In narcosynthesis barbiturates are administered intravenously as a means of facilitating psychotherapy. New and Kelly used this method in about 300 cases of acute war neuroses and a similar number of civilian cases with a wide range of disorders usually classed as psychoneurotic or psychosomatic. They gained the impression that narcosynthesis is of great value. Many patients obtain relief in a few days. With many others the period of treatment, although somewhat longer, is substantially shorter than if other methods are used. Narcosynthesis is one of the most practical and useful methods available in psychiatry, particularly with noninstitutionalized patients.

Intranasal Administration of Pertussis Antiserums in Mice.—According to North, mice have been shown to be suitable for the study of immunity in pertussis. Evans observed in 1944 a protective action of absorbed pertussis antiserum given to mice intranasally together with the infecting doses of Hemophilus pertussis. Evans concluded that both pertussis antibacterial serum and pertussis antitoxin are able to protect mice against infection by H. pertussis. North describes experiments carried out in an effort to confirm and extend Evans's observations. A high degree of protection against subsequent lung infection in mice is given by intranasal injection of pertussis antiserums. A lesser degree of protection is obtained when the serum is given after intranasal infection with H. pertussis. An absorbed human antibacterial serum protects mice better than a similarly absorbed antitoxic serum.

Occupational Hazard of DDT Spraying.—Gordon had an opportunity to investigate the toxic action of DDT in the field on a team of Africans who were occupied with spraying on five days of each week. Instructions were issued for personal protection against possible absorption by the wearing of gloves, gas capes and eye shields and for provision of an anti-drip can on the Mackenzie sprayer to catch the large amount of spray that ran back from the nozzle on to the operator's hands. However, no amount of ordering would convince these African civilians of the necessity for precautions. Blood examinations, regular weighings and skin inspections revealed that, although, these men were probably undernourished and took no precautions against skin absorption, no signs or symptoms of DDT poisoning were found. Slight increases in the leukocyte count were noted. When DDT was used in kerosene, rashes were common when sprayers first started on the work. After some months, however, they became desensitized. By means of a patch test it was shown that the irritation is primarily due to the kerosene and made considerably worse by the DDT dissolved in it. DDT alone is innocuous. A plea is made for the discontinuance of kerosene as a solvent for DDT.

d-Tubocurarine Chloride and Thiopentone in Electric Convulsion Therapy.—Hobson and Prescott describe the use of d-tubocurarine chloride and thiopentone for modifying electrical convulsions in 50 patients undergoing treatment for psychiatric illness. In all, 300 treatments were given. These drugs do not significantly affect the electrical convulsion threshold. The advantages claimed for the method are that the traumatic complications of electric convulsion therapy are avoided, there is no serious rise in blood pressure, it enables electric convulsion therapy to be given to certain patients in whom otherwise convulsions would be contraindicated, postconvulsive excitement is minimized, the procedure can be carried out single handed if desired and the unpleasantness of electric convulsion therapy for the patient is almost entirely eliminated.

Gold Salts in Reiter's Syndrome.—Willcox and his associates point out that in experimental animals certain strains of pleuropneumonia-like organisms give rise to arthritis and conjunctivitis. An attempt was made to isolate pleuropneumonia-like organisms from the conjunctiva and joint fluids of patients with Reiter's disease. Two patients with arthritis and urethritis, one of them also with conjunctivitis, have been investigated for the presence of pleuropneumonia-like organisms by culture of the joint fluid and blood on suitable mediums rich in animal protein and by inoculation of blood and joint fluid into mice. Apart from the production of arthritis in a single mouse by the injection of joint fluid from one patient, an investigation of 2 patients with Reiter's syndrome was negative for the presence of pleuropneumonia-like organisms. Since pleuropneumonia-like organisms have shown sensitivity to gold salts, injection of such salts was resorted to in 2 patients with Reiter's syndrome. This treatment was curative, while penicillin and sulfonamides were of little value.

Pattern of Olfactory Innervation. W. E. Le Gros Clark and R. T. T. Warwick.—p. 101.

Paget's Disease of Atlas and Axis.—Whalley says that, although Paget's disease commonly affects the vertebral column, it is rare for it to result in interference with spinal cord function. In an extensive search of the literature on the subject of spinal cord complications secondary to osteitis deformans the author has been unable to find any instance of the disease affecting the atlas and axis vertebrae and causing spinal cord compression. In the case described here, not only had the disease process produced cord compression, but it had also resulted in spontaneous forward dislocation of the head on the cervical spine. The patient was a man aged 66. The x-ray illustrates massive new bone formation, fusion of the vertebrae, kyphosis and dislocation of the head. Narrowing of the spinal canal can also be seen. The postmortem specimen shows encroachment of the bony overgrowth on the spinal canal and its contents.

Effects of Vitamin and Hormone Treatment on Senile Patients.—Vernon and McKinlay treated small groups of senile patients with vitamins B and C and with androgenous hormones. The patients, together with similar numbers of untreated controls, were tested individually with mental and psychomotor tests before treatment and during each phase of treatment. No evidence was obtained of any general improvement in intellectual efficiency or psychomotor capacities as a result of treatment. The only positive psychologic findings of this investigation were that moderate doses of vitamins may improve general mental ability among severe cases of senility, and may produce some increase in fluency and decrease in perseveration among light and moderate cases. Even these changes, amounting to about 10 per cent, are so much on the borderline of statistical significance that they cannot be regarded as proved without further evidence.

Modification of Human Red Cells by Virus Action: Agglutination by "Incomplete" Rh Antibody. C. M. Chu and R. R. A. Coombs.—p. 484.

Outbreak of Virus Encephalomeningitis.—An outbreak of neurotropic virus infections in which meningitic and encephalitic symptoms were prominent was observed between March and November 1946. In this outbreak 22 patients with meningitis or encephalitis and 13 with less clear signs and symptoms were admitted to the hospital. The cases occurred chiefly during the summer. In no case was it possible to trace a direct contact with another case in the family, school or work place. One peculiar coincidence was the admission of case 11 on the same day as a classmate who had clinical poliomyelitis. When the cases of encephalomeningitis were seen, an outbreak of poliomyelitis existed in the region and Brodie's statement that half the poliomyelitis cases in an epidemic are nonparalytic might suggest that the cases seen by the author were atypical forms of poliomyelitis. Most of the cases involved children or young adults. The illness usually began suddenly with fever and frontal headache. Though meningitic manifestations (headache, vomiting, photophobia and stiffness of the neck) were almost constant at this stage, they were sometimes not well defined. After admission the course of the illness was variable, but in most cases there was fever for about a week, and in many cases it was of low grade. Paul-Bunnell and Widal tests, done in some cases, were negative. Treatment appeared to have little effect. The weight of evidence is against these cases being due to an injection by the virus of Armstrong and Lillie. Whether one or more viruses were responsible for the infections also remains to be shown. The well known variations in the cerebrospinal fluid findings and the clinical picture, even in a recognized infection such as Armstrong's virus, and the number of neurotropic viruses as yet not isolated, make exact diagnoses difficult.

Scrub Typhus Vaccine.—Card and Walker say that with the realization in 1943 that scrub typhus would form a major medical problem in the war in Southeast Asia, work was started on the production of a vaccine. They describe a field trial with scrub typhus vaccine. Between July 1945 and February 1946 sufficient vaccine was distributed for the vaccination of over 60,000 men, though only 10,000 of these were inoculated on a controlled basis. As recommended by the Medical Research Council, 1 cc. of vaccine was given on three occasions at weekly intervals. No reactions were observed. There were 9 cases of scrub typhus in fully protected persons and 24 in partially protected persons. It is impossible on the limited evidence to say whether or not the vaccine has any effect on the mortality or incidence of the disease. The available evidence suggests that the vaccine has no noticeable effect on the clinical course or serologic reactions of scrub typhus.

*Mortality Rate of Appendicitis in Switzerland. S. Cuendet.—p. 565.
Contribution to Study of Fibromyoma of Cervix of Uterus. Bourg and Hannes.—p. 577.

Appendicitis in Switzerland.—The operative mortality rate of appendicitis in Switzerland was reduced progressively from 21 per cent at the end of the last century to 6 per cent in 1912, to 3 per cent in 1937 and to 1 per cent and even to less at present. The absolute mortality showed a pronounced increase up to 1937 in spite of the percental reduction of the operative mortality. Since that date up to 1944 the mortality has been reduced regularly. From 530 fatalities in 1937 it was reduced to 315 in 1944 in spite of the unfavorable conditions due to the mobilization of the army. According to Cuendet early diagnosis and early surgical intervention and better information passed on to the public may be responsible for this reduction, which preceded the introduction of the sulfonamides. In 1945 there was a mild increase of the mortality in spite of the use of penicillin, which became general in Switzerland in the spring of 1945. Three hundred persons are still dying from appendicitis in Switzerland yearly, with the majority of patients between the ages of 5 and 15; there is a progressive reduction of mortality in the next age groups and again an increase in the mortality of patients between the ages of 55 and 70 years. A critical study of 68 fatal cases from civilian life and from the federal military insurance revealed that in 51 death resulted from generalized peritonitis or from intestinal occlusion and in 15 per cent of the military cases from pulmonary embolism. In more than 50 per cent of the fatal cases operation was performed too late through their own fault or the fault of the family or because of difficult diagnosis. Obligatory preventive appendectomy in childhood does not seem feasible for the country as a whole, but individual preventive appendectomy is suggested, although one should keep in mind that it is not always without a risk.

*Treatment of Dyspnea in Asthmatic Patients with Theophylline. J. Turiaf and M. Bourel.—p. 109.

Theophylline in Asthma.—Turiaf and Bourel administered theophylline and theophylline ethylenediamine to 181 patients with asthma. One intravenous injection of 0.25 Gm. of theophylline in the morning and one in the evening, and one 0.35 Gm. theophylline suppository at noon brought radical relief of dyspnea in five to ten minutes after the injection and in fifteen to twenty minutes after the introduction of the suppository. This treatment was effective in 150 patients, 108 of whom had isolated paroxysmal attacks, while 38 had continuous dyspnea and 4 had effort dyspnea. Theophylline was effective in cases of severe asthma of ten years' duration in which pituitary-epinephrine preparations as well as procaine hydrochloride were ineffective. Untoward reactions did not develop. Thirty-one patients were failures, 25 of whom had continuous dyspnea and 6 had effort dyspnea. It is suggested that the highly satisfactory results obtained with theophylline may be partly due to its effect on the vasomotor apparatus of the epithelial lining of the bronchi.

*Heart and Hypovitaminosis B_1 in Pregnancy. F. De Matteis and E. Robecchi.—p. 201.

Heart and Hypovitaminosis B_1 in Pregnancy.—Twenty multiparous women with cardiac symptoms during the third and fifth months of pregnancy were given daily intramuscular or intravenous injections of from 20 to 30 mg. of vitamin B_1. Control of the subjective symptoms, return to normal pulse and disappearance of headache, edema and stenocardiac crises was obtained in the 13 patients who followed the treatment for one or two weeks. The failure in 7 patients was due to lack of cooperation and insufficient therapy.

•Primary Isolated Lymphogranulomatosis of Stomach. F. Farneti.—p. 3.

Lymphogranulomatosis of Stomach.—A man aged 38 had symptoms of gastric ulcer. He was in poor nutritional condition when the first vomiting of blood occurred. Four days later the second vomiting took place. It was profuse and caused his death. Necropsy showed fibrous fat infiltration of the stomach (especially the antral region), zones of necrosis and enlarged peripancreatic and perigastric lymph glands. The histologic diagnosis was lymphogranuloma.

•Infantile Poor Nutrition in Mexico. F. de P. Miranda.—p. 1.

Undernourishment of Infants in Mexico.—Undernourishment of infants and children of poor families dates back to remote epochs before the discovery of America. The most acute period is that of weaning, which is followed by chronic undernourishment up to the age of 6 years The mortality from infancy to the age of 6 years is high. Clinically there is a lack of proteins as the causal factor of disorders of somatic development, disorders of the type of fatty liver, diarrhea, a tendency to frequent infections, dehydration, edema and sometimes pellagra, ariboflavinosis and xerosis.

•Subacute Lymphoid Leukemia in Chronic Pulmonary Tuberculosis. I. M. Hernández and I. Smirnoff.—p. 677.

Lymphoid Leukemia in Pulmonary Tuberculosis.—The subject of this report, a man aged 30, presents the first instance of subacute lymphoid leukemia occurring in chronic pulmonary tuberculosis and the third instance of leukemia seen in the Hospital Tornú of Buenos Aires. The pulmonary tuberculosis was latent. The pathogenesis of lymphoid leukemia is not definite. In the reported case the clinical form was that of subacute lymphoid leukosis. Blood transfusions, sedatives and vitamins did not modify the course of the disease. Intercurrent bronchopneumopleuropathy was the immediate cause of death.

•Bronchiectasis in Children. S. A. Ayerbe Valles.—p. 11.
Myocardial Infarct in Adolescents. A. Crespo Alvarez and J. Márquez Blasco.—p. 39.

Bronchiectasis in Children.—Ayerbe Valles reports 13 cases of bronchiectasis in children between the ages of 7 and 12 years. Pleuritis, tuberculous adenopathies and tuberculous infiltration are the etiologic factors which bring about partial bronchial obstruction and local retention of secretions. The effect of atelectasis is indirect. The role of a congenital factor is possible. Blood spitting is an early symptom. Typical clinical symptoms manifest themselves in advanced periods. When a definite diagnosis cannot be made from a roentgenogram, x-ray examination after injection of iodized oil is indicated.

•Factors Affecting Mortality in Operation for Gastric or Duodenal Ulcer Without Acute Complications. J. L. Hansen, A. Boehm, H. B. Rasmussen and E. Ratjen.—p. 261.

Mortality in Operations for Gastric or Duodenal Ulcer.—Analysis of 531 cases in which operation was performed for ulcer without acute complications in three districts in Denmark during the last ten years, Hansen and his associates state, shows that of the factors which affect the mortality and can be influenced preoperatively the hemoglobin percentage, weight and stomach retention are especially important. If stomach retention cannot be overcome the prognosis is less favorable; gastroenterostomy may have to be done instead of resection. In underweight patients resection seems to be performed too often in proportion to gastroenterostomy. The factors which depend on how early and how often operation is done are of more basic importance in the question of mortality. The present work is an argument for earlier and more frequent operation. If there are repeated periods of increased activity, perhaps bleeding or perforation, if loss of weight and anemia occur, or achylia and retention, if the ulcer by x-ray manifests itself more clearly, and if rational medical treatment cannot cause the symptoms definitely to disappear, operation is advised. Before operation all means must be used to bring weight and hemoglobin count to normal and keep them so for a longer time, so that eventual general cell injuries can be repaired before the intervention. If these lines of guidance were followed a far larger number of ulcer patients would be operated on, considerably more milder cases and relatively fewer grave cases would be included, and a decline in the absolute number of grave ulcer cases would gradually follow.

•One Hundred Positive Hypoxemia Tests. G. Biörck and R. Pannier.—p. 315.
Vitamin C in Infancy. Irma Vitolin and L. Hesselvik.—p. 323.

Spinal Anesthesia with Nupercaine.—Fiil says that this form of spinal anesthesia gives definite effect for a longer period than do other forms and is therefore recommended for supraumbilical laparotomies. Of the 916 cases reported, 639 were supraumbilical and 277 infraumbilical. There were no anesthetic deaths. Collapse occurred in 18 patients but they all recovered. Jaundiced patients seem to be more liable to collapse after high spinal anesthesia. Injection of scophedal does not affect the occurrence of collapse but apparently aggravates its course. Collapse is independent of the amount of nupercaine used. Prophylactic injection of ephedrine is of no value. Two patients were refractory to the anesthetic. In 18 cases the anesthesia had to be supplemented with inhalation narcosis; 12 of these cases, also 12 of the collapse cases are ascribed to insufficient experience on the part of the anesthetist. The anesthetist should become apprehensive when the patient coughs, sneezes or is nauseated, as increased intra-abdominal pressure will cause the anesthesia to rise faster than intended.

Hypoxemia Tests.—The test was made on 666 patients, 378 men and 288 women. Of the 100 positive tests 40 were in men and 60 in women. Seventeen were in patients without suspected coronary disease, 53 in patients with suspected and 30 in patients with probable or certain coronary disease. Study of the positive tests shows a relative preponderance of women and a relative preponderance of patients with hypertension, especially in patients without suspected coronary disease. Positive tests in both men and women were more common in persons with heart of normal size than in persons with enlarged heart. In persons with enlarged heart an increased venous stasis in the coronary circulation may perhaps favor the development of collaterals. Seventeen patients, 16 of whom were women, are designated as neuropathic. While the hypoxemia is still considered a test of the function of the coronary circulation, a positive outcome does not necessarily mean organic disease; in some instances it is probably an indication of functional disorder.

Book Notices

Allergy in Theory and Practice. By Robert A. Cooke, M.D., Sc.D., F.A.C.P., Attending Physician and Director of the Department of Allergy, the Roosevelt Hospital, New York City, in Association with Horace S. Baldwin, and others. Cloth. Price, $8. Pp. 572, with 44 illustrations. W. B. Saunders Co., W. Washington Square, Philadelphia 5, 1947.

The author is a pioneer in the field of allergy, and this volume represents his experience and his teaching during more than thirty years. The book covers the theoretical and clinical aspects of the various allergic diseases, together with allergic factors in rheumatic fever, glomerulonephritis, tuberculosis and lupus erythematosus. A large part is given over to the fundamental aspects of allergy. The various theories regarding anaphylaxis, allergy and immunity are analyzed with great care. The role of histamine or some H-substance is discussed, but the author correctly points out that "actually there is as yet no convincing and confirmed proof that H-substance is liberated in the allergic wheal."

Much attention is given to serologic features of the immediate wheal-reacting allergies, pathologic-anatomic aspects of allergy and immunochemistry of antigens and antibodies. The various allergic conditions are then discussed individually, and this is followed by chapters on allergy due to bacteria, inhalants, foods, drugs, endocrine products, serum and physical allergy. There is also a chapter on skin testing and one on laboratory procedures.

Most of the book is by Dr. Cooke, but chapters also are written by thirteen associates. Asthma is divided into noninfective and infective, and a small but excellent concise pharmacopeia is attached. Morphine or other opium derivatives are advised in the treatment of severe bronchial asthma. Most allergists are strongly opposed to this advice; they have seen too many fatalities follow within a few hours after the needle has been inserted. Throughout the book runs the infection motif, this factor in allergy being more strongly stressed by the author than by most other allergists. This does not imply that the author is wrong. Cooke is almost certainly correct when he insists that true immediate positive whealing skin tests in "eczema" (atopic or intrinsic dermatitis) are not necessarily related to the dermatitis itself; they signify either associated or potential allergies which occur much more rapidly than does "eczema."

The fundamental and theoretical aspects of allergy are concisely stated. No other book is more authoritative in this respect. It summarizes all the important research work to date and points out some of the problems which need investigation. The clinical section of the book is also good but is not as distinctive. It lacks many of the details which would enable general practitioners to cope successfully with difficult allergic problems. Skin testing, according to Spain, one of the co-authors, should be done only by the intracutaneous method. He states (page 109) that "by experience it has been learned that the potencies adopted (of various extracts) are quite safe except for the occasional, exquisitely sensitive person who can usually be identified before testing by points in his clinical history." That this statement leaves something to be desired is shown by continuing case reports of death or anaphylactic shock after intracutaneous skin tests. Much to be preferred is the statement in the same book (page 502) by Walzer, another co-author, that "the scratch test is by far the safer method for the novice who is not fully cognizant of the dangers of testing and of the steps for preventing and counteracting untoward reactions which may result from the procedure." The chapter on migraine, from the standpoint of allergy, has a defeatist point of view; the importance of allergy is belittled, this despite the many reports of complete relief from attacks when the food has been discovered and avoided. Details regarding elimination diets or diet records should be given in this chapter.

The book is strongly recommended to all interested in the field of allergy and is a must for those who are especially concerned with studies of immunology. It is well written, concise, well printed and nicely illustrated. It has many good case reports and references.

Elements of Genetics: Mendel's Laws of Heredity with Special Application to Man. By Edward C. Colin, Ph.D. Second edition. Fabrikoid. Price, $3.50. Pp. 402, with 90 illustrations. Blakiston Co., 1012 Walnut St., Philadelphia 5, 1946.

This book is attractive in format and generously illustrated with diagrams, drawings and well chosen photographs. The author presents clearly and concisely the principles of heredity. He includes an up to date discussion of cytogenetics, the nature and causes of mutations, the relative roles of environment and heredity, inbreeding and crossbreeding, and factors involved in evolution. The important subject of probability is presented with unusual clarity. The historical material, particularly the contribution of Mendel, is skilfully used as a basis for presenting genetic principles. Fully half of the book is devoted to a discussion of human heredity. Included here are hereditary characteristics of skin, hair, nails, teeth, eyes, skeleton and muscles and of the circulatory, respiratory, excretory, endocrine, digestive, reproductive and nervous systems. Hereditary factors in cancer and other diseases are considered. Examples of human sex-linked factors, those on the X and the Y chromosomes, are given. However, Haldane's interesting work on partially sex-linked factors and his mapping of the homologous section of the X and Y chromosomes are omitted. The medical man will find this book of unusual interest in that it presents clearly the principles of heredity and then shows their application to the human body in health and disease.

The final chapter on improvement of the human species deals with both negative and positive eugenics. Exception might be taken to certain implications concerning immigration laws and the subsidization of families of the so-called fit. However, the analysis of the role of negative eugenics, marriage restrictions, segregation and sterilization in reducing different types of hereditary defects in a country is exceptionally well presented. If carefully studied, the contents of this book could be highly illuminating to those medical practitioners whose training has not included a course in genetics. It is particularly recommended to young men in medicine or intending to enter this field.

La chirurgie en obstétrique. Par R. Keller, professeur de clinique d' obstétrique et de gynécologie à la Faculté de médecine de Strasbourg, et A. Gínglinger. Préface du P^r Reeb. Paper. Price, 230 francs. Pp. 232, with 79 illustrations. Masson & Cie, 120 Boulevard Saint-Germain, Paris 6^e, 1916

This book does not deal with obstetric operations such as forceps deliveries but with surgical procedures for complications that occur during gestation and also with operations for conditions that prevent pregnancy. The authors describe and in most cases illustrate operations for (1) malformations of the genital organs such as imperforate hymen, stenosis of the vagina and cervix, absence of the vagina and double vagina or uterus, (2) acquired sterility due to inflammatory disease, neoplasms and retroflexion, (3) special obstetric conditions which can be remedied by surgical procedures such as ectopic pregnancy, fixed retroflexed gravid uterus, hydatid mole and chorionepithelioma, (4) complications of pregnancy which can be corrected surgically, including appendicitis, intestinal obstruction, cancer of the cervix, fibromyomas of the uterus and ovarian cyst, (5) soft part and bony dystocia at the end of pregnancy and during labor, including cesarean section, symphysiotomy and means of treating placenta previa, abruptio placentae, rupture of the uterus and other conditions, (6) postpartum infections such as uterine abscess, phlebitis, peritonitis and pelvic abscess and (7) noninfectious complications after labor such as inversion of the uterus, vesical and rectal fistulas and perineal lacerations.

A large portion of the book deals with rare conditions, some of which are never encountered even in the lifetime of obstetricians of long experience. The only operations illustrated for constructing a vagina are those of Schubert and Baldwin-Mori, both of which are now obsolete because much simpler and safer operations exist. Likewise, the Braxton Hicks version should be discarded for the treatment of placenta previa. Since this is a book dealing with surgery there should be more illustrations. Nevertheless the book is well written, and the advice given is generally practical and useful. It should be helpful to obstetricians and surgeons who can read French.

Textbook for Psychiatric Attendants. By Laura W. Fitzsimmons, R.N., B.S., M.A., Assistant Director of Nurses, and Chief Neuropsychiatric Nurse, United States Veterans' Administration. Cloth. Price, $3.50. Pp. 332, with 2 illustrations. Macmillan Company, 60 Fifth Ave., New York 11, 1947.

Although this volume is said to be designed for attendants in mental hospitals, the treatment of topics is strongly reminiscent of books of instruction for psychiatric nurses. The vocabulary is occasionally erudite and will not be readily understood by many attendants; e. g. "patients who are cognizant of their surroundings" (p. 148), "interproximal surfaces of the teeth," "upper lingual surfaces" (p. 249). On the other hand, phrases are used which are not in good repute in schools of nursing, such as "a patient is diagnosed as having . . ." (p. 31). It is not good form today to refer to patients as "cases" (pp. 34 and 192) but rather to speak of persons having symptoms or disease conditions. As a textbook it leaves something to be desired. The index is incomplete. The only item which in any way refers to medications is "labels, medicine," although "administration of medicines by mouth" appears on pages 296-299. In view of the importance given today to the use of visual aids as a desirable teaching aid, it is unfortunate that there are no diagrams or illustrations to help the attendant in either the nursing procedures or the management of patients. There should be a considerable demand for a textbook for psychiatric attendants. If the demand meets expectations, the book should be carefully edited to fulfil successfully the requirements of the trainee attendant before the publishing of a second edition.

Early Ambulation and Related Procedures in Surgical Management. By Daniel J. Leithauser, M.D., F.A.C.S., Chief of Surgery, St. Joseph Mercy Hospital, Detroit, Michigan. Cloth. Price, $4.50. Pp. 232, with 36 illustrations. Charles C Thomas, 301-327 E. Lawrence Ave., Springfield, Ill., 1946.

This is a highly personalized account of the experience of one surgeon with early ambulation postoperatively. The author does not claim priority, and indeed, many surgeons have long practiced some form of early rising after operation. This does not mean a shortening of the accepted lengthy stay in bed by a few days but involves a systematic attempt to force (better persuade) even reluctant patients out of bed within a few hours after operation. The advantages of such procedures are now generally recognized and need not be detailed here. Early ambulation has thus become the preventive phase of physical rehabilitation by preventing the debility associated with confinement to bed for any long period. The author outlines briefly some historical features of the technic and the physiologic principles forming the scientific basis for the method. He is a strong advocate of the transverse incision, and the use of steel wire for closure of laparotomy wounds. The particular relationship between these two features, especially the second, and early rising is a matter of some controversy. Most important in the whole scheme is the nursing care. When nurses understand the importance of early ambulation and are properly trained to assist the patient in his first few attempts, the method will be spectacularly successful. This the author emphasizes. The results of his experiences are analyzed and are impressive.

Medical Services by Government: Local, State, and Federal. By Bernhard J. Stern, Ph.D. Studies of the New York Academy of Medicine Committee on Medicine and the Changing Order. Cloth. Price, $1.50. Pp. 208. Commonwealth Fund, Division of Publications, 41 E. 57th St., New York 22; Oxford University Press, Amen House, Warwick Sq., London, E. C. 4, 1946.

This is one of many monographs published in recent years by the Commonwealth Fund under the auspices of the Committee on Medicine and the Changing Order of the New York Academy of Medicine. The author traces briefly the development of governmental responsibilities for medical services from the poor laws of the colony days to the present time. The repressive features of the early poor laws have never quite disappeared from government medical service, particularly at the state and local levels. Local responsibility still prevails and, according to the author, "has led to wasteful multiplicity of small administrative jurisdictions." The assumption by state governments of more and more responsibility in the field of medical services has been instrumental in extending the scope beyond the indigent. Data on expenditures of government agencies for medical services are fragmentary; yet they seem to bear a direct relation to the per capita income of the area. A short but comprehensive picture is given of the extent of government participation in the provision of hospital services. The phenomenal growth in government hospital facilities, the change in public attitude toward such institutions and the resulting demand for more adequate services has brought about a vast federal grants-in-aid program. This program is traced in detail. Considerable discussion is also given over to the medical services traditionally provided by the federal government. Dr. Stern has done an excellent job in tracing the shifting role of the local, state and federal governments in the field of medical care. One of the few criticisms that can be made is that throughout the entire discussion he has dealt with medical care in terms of dollars, facilities, statutes and agencies with too little recognition of the role of the physician as an individual and as a member of a profession.

A Psychology of Growth. By Bert I. Beverly, M.D., Rush Assistant Professor of Pediatrics, College of Medicine, University of Illinois, Chicago. Cloth. Price, $2.50. Pp. 235. McGraw-Hill Book Co., Inc., 330 W. 42d St., New York 18, 1947.

This book attempts to present the psychology of growth and development in a way which will help nurses to gain an insight into their own problems as well as those of their patients. It traces human growth and development from infancy, through childhood and adolescence to maturity. The first six chapters deal with the foundations of mental health, the 2 year old, adjusting to environment, intelligence, mental deficiency and the school child. In the remaining portions of the book fears, behavior problems and their causes, preadolescence, adolescence, juvenile delinquency and adult adjustment are discussed. A rather complete list of visual aids is included to supplement the material in the text. References for additional study are provided at the end of each chapter. The author uses a very practical approach to solving problems that may be encountered at various age levels. Numerous examples serve to illustrate methods of meeting individual needs at various stages of growth and development. Throughout the discussion stress is laid on the interdependence of mental, emotional and physical aspects of personality development. The book is clearly written and well printed. While it is not illustrated, the potentialities for correlation with the suggested visual aids offer many possibilities. It will probably have its greatest usefulness as a textbook for courses in psychology and in professional adjustment and as a reference work for the graduate nurse working in the field of pediatrics, psychiatry or public health. However, it may be read with profit by social workers, teachers and parents.

Complete Handbook on State Medicine. By J. Weston Walch. Paper. Price, $1.25. Pp. 170. J. Weston Walch, Box 66, Pearl St. Station, Portland, Maine, 1946.

This brochure is primarily for students preparing material for debate on the subject of "sickness insurance." It represents a new approach in debate manuals or at least a composite of most of the usual approaches. In an effort, a rather successful effort, to make the debate question interesting to the readers the author presents his material in a casual manner. One example is the title of chapter I, "Ho, Hum, What's the Argument All About?" Another is his introduction to the Wagner bill. "A cat, they tell me, has nine lives, though you can't prove it by me. But this I do know—the Wagner-Murray-Dingell bill has had three." Throughout this informal presentation there is a great deal of factual data. Numerous references are made to well chosen sources for additional material. In the first thirty-two pages Mr. Walch explains the debate question and the terminology, discusses briefly the present systems of medical care and gives suggestions for preparing the debate. Much of the remainder of the publication is devoted to the preparation of both affirmative and negative briefs with supporting evidence, and references accompanying each brief. The final few pages contain suggestions for rebuttal. In presenting the supporting evidence the author has sacrificed completeness in order to use as many quotations as possible. Three hundred and forty-seven quotations appear for the affirmative and three hundred and forty-four are used in support of the negative. Too often they are one sentence statements plucked from some one's talk or article which, if read as a part of the whole, might mean something different than intended. Aside from this criticism, the publication is well done and should be in the hands of every debater.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

"PAINLESS" CORONARY OCCLUSION

To the Editor:—One wonders how many persons suffer "silent" coronary infarction. By that one means coronary thrombosis and infarction in which symptoms are absent, so slight or so atypical that the heart is not suspected or at least a definite diagnosis of coronary disease is not made. This question could be answered knowing how often scars of old infarcts are found in hearts of those in whom coronary thrombosis was never diagnosed during life. Such figures are probably available in many reports by pathologists, but I am unable to find any such report listed in the indexes. I would appreciate information on the subject.

D'Arcy Prendergast, M.D., Toronto.

Answer.—Painless or silent myocardial infarction due to coronary occlusion does exist, but its exact frequency has not yet been established. At times its occurrence has certainly been overestimated as the result of inadequate history taking. Most experienced observers who have seen hundreds of cases of acute myocardial infarction find that painless or silent acute coronary occlusion is distinctly uncommon. It may occur in the presence of severe shock and possibly severe acute alcoholism and quite possibly, but infrequently, in extremely insensitive persons. Its occurrence otherwise must be open to question. Two cases reported not long ago from Seattle (King, R. L., and Cleveland, F. E.: Acute Coronary Occlusion Without Pain, *Clinics of the Virginia Mason Hospital* **24**:35, 1946) occurred in diabetic patients; the first patient was intermittently unconscious and the second patient was quite drowsy, doubtless affected by an inadequately controlled diabetic state.

A recent review of 78 cases of myocardial infarction at the Massachusetts General Hospital in which necropsy was performed gave no history of pain in 9, with serious shock or coma or cerebral vascular accident present in 10 others in which pain could not be inquired about.

VESICAL AND PROSTATIC CANCER

To the Editor:—In the Jan. 25, 1947 issue of The Journal on page 279 vesical and prostatic carcinoma is discussed. The following questions relate to that subject: 1. When the spread is along the ejaculatory ducts what are the early and late symptoms besides being able to palpate the growth in the prostatic notch? 2. What would be the difference in the early and late symptoms when the metastases occur along the vertebral system of veins instead of along the ejaculatory ducts? 3. What is meant by the term "median bar" of the prostate? Is it prone to become cancerous more than any other portion of the prostate and if the median bar is somewhat enlarged is it as likely to be benign as to be malignant? 4. In a transurethral resection of the prostate is the ejaculatory function of the ejaculatory duct permanently lost? 5. Babcock's Surgery speaks of an early cystitis. Once cystitis is established I take it that the condition is intractable and remains a symptom in spite of any and all treatment medically. Is this true? 6. Is the prostate considered one of the genital organs?

M.D., Kansas.

Answer.—1. The spreading of carcinoma along the ejaculatory ducts could indicate its origin in the posterior lobe. Cancer of the posterior lobe is manifested by induration and obliteration of the median prostatic groove proximal to the veramontanum. Early symptoms of carcinoma of the prostate may be absent. Extension along the ejaculatory ducts may easily produce unexplained distention of the seminal vesicles. Carcinoma may be suspected early when the prostate is palpated over an instrument and a nodule is present.

2. Early symptoms of metastases by way of the vertebral system of veins may be limited to localized pain. Early x-rays of the spinal column will be negative. Later osteoclastic bone changes will confirm the suspicion of metastases.

3. A median bar implies hypertrophy of the posterior commissure of the prostate. A median bar is not apt to become cancerous; the enlargement is usually benign and consists of fibrous or adenomatous tissue.

4. The function of the ejaculatory duct following transurethral surgery is not lost unless it is inadvertently removed.

5. Hunner's ulcer or interstitial cystitis with a contracted bladder has been referred to as an intractable cystitis. Cystitis is usually amenable to treatment, particularly when the cause can be eradicated.

6. The prostate is a male sex organ and is a link in the male genital system.

DISPOSAL OF SEWAGE AND WATER BORNE DISEASE

To the Editor:—I should like your opinion on the following two statements:

1. It has been estimated that 70 per cent of sewage in the United States is dumped into surface waters without treatment.

2. In spite of the health hazards involved, the practice has been continued because of the cost of treating sewage.

Is the A. M. A. cognizant of this practice? Is there a greater prevalence of water borne diseases in those areas of the United States where sewage is dumped into surface waters without treatment? If so, should not the public be enlightened with regard to this practice with the hope that it would insist on effective sewage control systems regardless of cost?

David J. Sandweiss, M.D., Detroit.

Answer.—1. The sewage of somewhat more than 50 per cent of the total urban population of the United States is now treated, either by what is known as partial treatment or by complete treatment.

2. The practice of discharging raw sewage has been continued not only because of the cost involved but because of a variety of complex legal, administrative and fiscal issues. Cost is a significant item in these considerations, but not the only item. Progress in correcting this situation has been materially retarded during the war period and, in the present high level costs of labor and materials, in the postwar period.

Administrative attack on the problem, however, continues at a high level and it may be anticipated that the next ten years will see billions of dollars expended in correcting the situations to which you refer.

The American Medical Association is cognizant of the practice and is lending its efforts toward increasing the rate of correction. Water borne diseases in general in the United States are now at their lowest point in our history, as the result obviously of the combined efforts of engineering and medical officials over the last half century.

SENILE OSTEOPOROSIS OR HYPERPARATHYROIDISM

To the Editor:—A woman aged 57 injured her back three years ago and since that time has had constant back pain and progressive kyphosis. X-rays of the skull and lumbar spine showed loss of normal bone density. The tables of the skull were mildly granular, suggesting the possibility of low grade hyperparathyroidism. Blood calcium was 10 mg. per hundred cubic centimeters, inorganic phosphorus 2.8 mg. per hundred cubic centimeters and serum alkaline phosphatase 46.3 Bodansky units. Is this the picture of senile osteoporosis or hyperparathyroidism? How may I further establish the diagnosis?

John Shelton Reed, M.D., Kingsport, Tenn.

Answer.—The high serum alkaline phosphatase level is against senile osteoporosis. Furthermore, one seldom sees demineralization of the skull in that condition. The normal serum calcium level is against hyperparathyroidism unless the patient had at the same time a low serum protein level. The blood findings are consistent with osteomalacia.

To establish a diagnosis, one would like repeat serum calcium, phosphorus, phosphatase determinations, a serum protein determination with albumin/globulin ratio if possible, and a quantitative twenty-four hour urine estimation for calcium. A low serum calcium excretion would be strong evidence against hyperparathyroidism, moderate evidence against osteoporosis and strong evidence in favor of osteomalacia. A high urinary calcium excretion would not rule out osteomalacia, however.

COSMETIC EFFECT AFTER REMOVAL OF FACIAL CYST

To the Editor:—Has any satisfactory method been developed for removal of a sebaceous cyst from the skin without leaving a scar or other disfigurement? The patient is a pretty young girl of 18 who has a sebaceous cyst about the size of a lima bean in the skin of the cheek. This was recently infected, red and tender but is now quiescent and painless. My previous experience has been that excision is always followed by some scarring, which it is hoped to avoid in this case. At present the nodule is not too unsightly, but it seems to cause her a great deal of concern.

Willis P. Baker, M.D., Santa Ana, Calif.

Answer.—There is no possible way to remove a cyst of this type without an incision through the skin. The best cosmetic result can be obtained if the line of incision is placed so that it will parallel a normal skin fold or wrinkle. The size of the incision should be made as small as will permit legitimate exposure of the tumor. Minimal postoperative scarring can be obtained if the wound edges are sutured with small interrupted stitches of fine nonabsorbable suture material. The stitches should be removed within three days so as to avoid potential stitch hole scarring, but the wound edges should be supported with some material such as a dumb-bell strip of adhesive for two to three weeks postoperatively. Failure to carry out the latter step may permit the fresh scar to widen from underlying muscle activity.

CELLOSOLVE ACETATE

To the Editor:—I should like information as to the possible toxic effects of the fumes of heated Cellosolve Acetate on industrial workers. The process consists in heating 20 gallons of the chemical to 50-60 C. and then rapidly cooling it with solid carbon dioxide. Is it possible for taste, smell, the eyes and sexual potency to be affected by the fumes engendered? Would the toxic effects be permanent?

M.D., New Jersey.

Answer.—Published information on the toxic properties of Cellosolve Acetate (ethylene glycol monoethyl ether monoacetate) derives from animal experiment rather than from human beings actually exposed in industry. The vapor pressure of Cellosolve Acetate at 20 C. is 1.25 mm. of mercury, which is low. Obviously vapor pressure at 60 C. will be higher. According to Von Oettingen and Jirouch (*J. Pharmacol. & Exper. Therap.* **42**:355 [Aug.] 1931) it hemolyzes blood in vitro and causes the formation of methemoglobin. It has a distinct depressant effect on the central nervous system and causes, first, irritation and then depression of the sensory nerve endings and paralysis of the motor nerve fibers. It depresses the perfused frog heart and organs with smooth muscle structure. It causes distinct irritation of the conjunctiva of the rabbit's eye, characterized by hyperemia and edema of the lower eyelid. There are no reports with regard to the toxic action in man, but the data mentioned appear to indicate that it is by no means a harmless material. Hamilton and Johnstone (New York, Oxford University Press, 1945) in referring to the work just cited note that repeated exposures of rats to vapors of glycol ethers, 300 to 400 parts per million, show that "small but measurable effects" on the cellular elements of the blood appear, such as increase in young granulocytes and decrease in hemoglobin concentration and red cell count.

Browning (British Research Medical Council Report number 80, 1937) places the toxicity level as that of Cellosolve (ethylene glycol monoethyl ether). The toxicity of the latter is well established and is revised by Browning. Still further information derives from the work of Smyth and others (*J. Indust. & Toxicol.* **23**:259, 1941). This group determined the MLD/50 on small animals for some sixty glycols and related compounds. Cellosolve Acetate proves to stand about midway in the group. The vapors of Cellosolve Acetate may lead to eye irritation and may influence taste and odor perception. Higher concentration may serve as a central nerve depressant and may act adversely on the renal system. Deviation from the usual in the blood picture may constitute a prime warning of damage. It is unlikely that this substance will exert any direct influence on sexual capacity.

ADMINISTRATION OF HISTAMINE IN PRESENCE OF CORONARY DISEASE

To the Editor:—In recent months there has appeared in the lay press some reference to the use of histamine in the treatment of patients who complain of dizziness that is otherwise unexplained. I have under my care such a person but who has had in recent years two episodes of coronary artery disease, and I have hesitated to give him histamine in an effort to overcome these attacks of dizziness because of the fact that I was afraid there might be some danger associated with it.

Oliver L. Sharp, M.D., Greensboro, N. C.

Answer.—In the heart-lung preparation of human beings, histamine dilates the coronary arteries. Presumably the same action occurs in the living subject.

Patients with Ménière's disease and coronary heart disease have been given a 1:250,000 dilution of histamine administered intravenously without producing untoward symptoms. The rate of administration should be carefully regulated.

Peters and Horton recently published a report on 25 normal subjects in whom continuous intravenous administration of histamine was given at rates varying from 0.0017 to 0.044 mg. per minute. Significant changes were observed in the electrocardiograms in 24 of the 25, but the effects were considered to be of minor physiologic importance. The most common change was the loss of amplitude of the T waves in different leads, sometimes in all leads, which, in some cases, proceeded to either the isoelectric level or to inversion of the wave. The extent of loss of T wave voltage was roughly and directly parallel to the rate of administration of histamine. In some cases, however, the effect of histamine was lost, and the T waves recovered either partially or completely their former amplitude in spite of a continued and sometimes increased dosage of histamine. The effect of histamine on the T waves disappeared within five to fifteen minutes after injection of the drug was discontinued.

The action of histamine on coronary circulation varies in different species. Essex and his colleagues found that histamine increased the coronary flow in the unanesthetized dog.

POSTRADIATION TREATMENT OF CARCINOMA OF CERVIX

To the Editor:—A woman aged 40, who weighs 80 pounds (36 Kg.), has a grade 1 squamous cell carcinoma of the cervix apparently early and confined to the cervix. Six months ago she was treated with 5,000 mg. hours of radium and 4,500 roentgens of x-rays, half value layer 1.5. There is no evidence of recurrence of cancer. The cervix has healed. Is total hysterectomy advised at the present time?

G. B. Hubbard, M.D., Jackson, Tenn.

Answer.—Although the cervix may appear to be entirely healed, Martzloff has shown that viable tumor cells may remain entrapped within the cervix and cause recurrence at a later date. The patient described in the query, because of age, weight and an apparently early lesion, is an ideal subject for the radical hysterectomy of the Wertheim type. Therefore one could not disagree with those who would favor removal of the uterus by this procedure. However, the high survival rate (80 per cent) of patients with such early lesions treated with radium and x-rays in adequate dosage, such as has been given this patient, justifies watchful expectancy, postponing surgical removal until definite evidence of recurrence can be demonstrated.

INFECTIONS AMONG PATHOLOGISTS AND MORTICIANS: WEARING OF RUBBER GLOVES

To the Editor:—Are there any statistics available showing the incidence of infection which morticians and pathologists have sustained from working on corpses? It is assumed that chemical changes set in shortly after death and that organisms are not viable long. However, there are occasions when morticians get tuberculosis, and there is a question in their mind as to the source of such infection, not only of tuberculosis but of other infections. A coroner contends that the practice of using gloves in examining bodies is the wrong practice, as the prick of a glove and finger makes for optimum conditions of culture medium, thus reviving the organisms sufficiently to be viable and pathogenic and making it possible to transmit infection to the examiner. This has raised some controversy in a mortician's organization. Any information you can give on this matter will be of help and interest.

J. A. Cremer, M.D., Denver.

Answer.—Statistics showing the incidence of infection (including tuberculosis) which morticians and pathologists have sustained from working on corpses have not been found. There are isolated cases of tuberculosis among embalmers. Some believe their infections traceable to given instances. Similarly, instances are known wherein embalmers and pathologists respectively have acquired infection as the result of an accidental wound during embalming procedure or while conducting a postmortem examination.

In supporting the hazardous concept of the embalmer's occupation, insurance classifications offer a clue. The majority of companies who write health and accident policies regard men in this occupation as class C and D risks.

Several years ago the question concerning the value of rubber gloves as a safety measure was raised in another mortician's organization. Again statistics were not available for supporting either point of view. Nevertheless an opinion given by an eminent pathologist was to the effect that there could be little question that pathologists suffered many more hand infections than physicians in general. He always wore gloves. He believed that organisms which would produce an infection of the hand are deposited within the skin when the finger is pricked and that they are uninfluenced by warmth and moisture of the hand and glove.

Between 1932 and 1935 at the Los Angeles County General Hospital there was a difference of opinion among the classes, particularly between those who had worked around a funeral home before enrolling in school, as to the merit of rubber gloves. However, every student was required to wear them while in the preparation room. The importance of caring for gloves properly while in use and in cleansing them for subsequent use was stressed. During this interval approximately two hundred students received their practical training in preparing all types of cases. Only one instance of infection was reported. It was not due to accident while wearing rubber gloves.

There is sufficient periodic interest in this subject to justify a bona fide investigation to settle this long controversy.

MENSTRUATION AND BATHING

To the Editor:—Aside from the esthetic factors, is menstruation a contraindication for bathing, particularly in cold water, or swimming?

M.D., Iowa.

Answer.—Menstruation is not a contraindication to any form of bathing except when the flow is profuse. In such cases a hot tub bath might increase the loss of blood still further.

OPEN VERSUS CLOSED TREATMENT OF FRACTURES

To the Editor:—*Has it ever been definitely proved that simple fractures treated by open reduction heal more slowly than simple fractures treated by closed methods, comparing, of course, fractures of the same site, degree of severity and patients of similar age groups? That fractures treated by open operation heal more slowly has seemed to me to be quite evident, but there are so many variable factors it is difficult to prove the point.*

Herbert J. Forrest, Lieutenant, M. C., U. S. Army.

Answer.—The point has not been definitely proved but is suspected by some experienced surgeons and laughed at by others. Advocates of the open method often disclaim slower healing and claim on the contrary more rapid repair, saying that perfect reduction, supposedly obtained by operation, calls for less effort on the part of the patient to form callus. This is because the perfect approximation of fragments requires a smaller amount of new bone formation, there are smaller gaps to bridge and the various bone elements are closely apposed. They also may claim that shorter immobilization is required and earlier use of the part is permitted to restore muscle volume and increased blood supply in the area. Many catastrophes have resulted from loose and unskilful application of this so-called principle because it provides a too short immobilization and defeats the process of healing itself by permitting too early and too great strain at the fracture site.

The most difficult factor to weigh is the bone forming power of any single person even in the same age group. There may also be a minimal degree of totally unrecognized infection. One still unmeasured factor is the loss at (early) operation of much if not all of the extravasated blood and exudate around the fracture site, amounting in major fractures to several ounces, which runs out as soon as the fracture is cut down on. This contains not only calcium and phosphates but also phosphatase useful in the healing process and probably has much to do with sustaining a favorable p_H in the early part of the repair.

No line of treatment seems to hasten the normal process of final complete calcification of callus after closed fracture in healthy persons, but many factors such as nonexpert operating, too short immobilization or unwise weight bearing or use may prolong it. This does not apply to greatly delayed union or nonunion.

TREATMENT OF CARBON MONOXIDE COMA

To the Editor:—*Which are the therapeutic measures at present adopted in the United States in cases of coma from carbon monoxide? Are the blood transfusions still used?*

Jean Enderlé, M.D., Brussells, Belgium.

Answer.—In cases of coma due to carbon monoxide poisoning it is important to supply 100 per cent oxygen or 7 per cent carbogen (7 per cent CO_2+ 93 per cent O_2) as quickly as possible to support the heart and to remove the carbon monoxide from the blood. It has been found that as far as immediate survival and neurologic sequels are concerned it matters not which of the two gases is used. In either case (which is also true if air is used) it is important to keep the minute volume of pulmonary ventilation as high as possible without harming the lungs for a period of five to fifteen minutes. By the end of this time the carbon monoxide saturation of the blood has been reduced to safe limits (5 to 10 per cent) and if the patient is still in coma blood transfusion will not be of assistance unless the patient is in a state of circulatory shock. Blood transfusion has no place in the treatment of carbon monoxide asphyxia in the absence of circulatory shock. Coma may sometimes persist for two or three hours after the oxygen saturation of the blood has returned to 90 per cent in the presence of a normal blood pressure, following which full functional recovery may result; the cause of this coma is uncertain. The prognosis is grave as regards neurologic sequels if the coma persists longer than thirty minutes after the reduction of the oxygen saturation of the blood to 90 per cent.

SULFHYDRYL FOR ROENTGEN RAY BURNS

To the Editor:—*Is sulfhydryl of value in the treatment of chronic x-ray burns of the hands? (Cruthiras, A. E.: Importance of Sulfhydryl in Treatment of Corneal and X-Ray Burns, Am. J. Surg. 72:500 [Oct.] 1946; abstr. The Journal, Jan. 11, 1947, p. 131.) Is straight sulfhydryl sprayed on ulcers or is penicillin used in 1:1 spray? What strength penicillin is used and how is it mixed?*

Robert H. Kerr, M.D., Alma, Neb.

Answer.—The article to which reference is made in the query is the only report available on treatment by sulfhydryl of lesions produced by roentgen rays. Until further reports are available the treatment must be considered experimental, but apparently it is quite harmless. It appears from the original article that when penicillin is used it is applied in solution separately from the sulfhydryl spray and ointment.

TOXIC ADENOMA OF THYROID AND PROPYL-THIOURACIL

To the Editor:—*A patient with a toxic adenoma of the thyroid gland developed a universal pruritus on taking thiouracil in doses as low as 25 mg. daily. Is there any other related compound that may be used in place of thiouracil? If there is, please give me the dosage and untoward effects.*

Morris I. Gerner, M.D., Chester, N. Y.

Answer.—One could try propyl-thiouracil. This is begun with a dose of 50 mg. three times a day. It is sometimes necessary to give as much as 200 or 300 mg. daily to produce the maximum effect. It should, however, be borne in mind that response to this drug may be rather slow, particularly by a patient with toxic adenoma. The reactions produced by propyl-thiouracil are approximately those produced by thiouracil except that they occur less frequently.

The most serious complication is the development of leukopenia and agranulocytosis, and patients receiving the drug should be observed with great care. A white blood cell count and a differential count should be made at frequent intervals.

There is some difference of opinion as to whether the drug should be used for the medical management of patients with toxic adenoma. It is probably fair to say that the majority of observers favor using it for preoperative preparation in this condition. However, there is no doubt that in many patients with toxic adenoma the condition can be controlled completely with medical measures alone.

SPLENIC ANEMIA AND PREGNANCY

To the Editor:—*A woman aged 27 is three months pregnant. This is her third pregnancy. The patient's first child died at three months of splenic anemia and "enlarged liver." In the patient's second pregnancy labor was induced at eight months and the child lived for five weeks, probably dying of pneumonia. My patient has splenic anemia. The patient's father died of splenic anemia. The patient has had two series of x-ray treatments and two transfusions; she has been taking daily liver injections for four years; also she is getting folic acid 5 mg. three times a day. She is anxious to permit pregnancy to go to term and will take transfusions as indicated, also other therapy. Should pregnancy be permitted to continue? If so, what should the course be?*

M.D., Asheville, N. C.

Answer.—In the absence of data concerning the blood picture it is difficult to suggest the proper therapy for the anemia. It is assumed that the patient's blood is now normal from the daily injections of liver extract for four years and the folic acid. Ordinarily it would be wise to allow the pregnancy to continue unless the anemia becomes extremely severe and cannot be controlled by transfusions, or the size of the spleen limits the space in the abdomen to such an extent that with the enlarged uterus the discomfort is too great. It may be well to investigate the Rh factor in the blood of the patient and her husband before more transfusions are given, as she may be Rh negative and have developed anti-Rh substance from the previous transfusions (if they were Rh+).

SKIN STAINING FROM FRUIT JUICES

To the Editor:—*I am seeing a few patients who work in a fruit preserve factory. From contact with fresh fruits, their hands become stained dark. Is there any way to prevent or decrease this staining?*

Albert Abraham, M.D., Morristown, N. J.

Answer.—The wearing of rubber gloves with impervious sleeves fastened over the glove at the wrist will prevent the fruits or their juices from touching the skin.

Washing the stained hands after work in a 1:2,000 solution of potassium permanganate followed by washing in a 1 per cent solution of sodium sulfite to remove the permanganate stain will bleach the stains. After this procedure the hands should be washed in soap and water and dried, and an emollient cream such as equal parts of lanolin and cold cream should be rubbed into the skin.

MANNITOL HEXANITRATE

To the Editor:—*In The Journal, April 5, 1947, page 1042, a query discusses mannitol hexanitrate for hypertension. I believe that the opinion given in the answer is not in accordance with generally accepted views with regard to the action of compounds of this type. In the answer the statement is made that the nitrite ion is extraordinarily unstable. This is not in accordance with fact. Also the statement is made that the concentration of nitrite ion in the blood is in the order of magnitude of 1 microgram per hundred cubic centimeters. This has been found to be incorrect also. Further, it is stated that why some of the compounds are more active than others is not well understood. The mechanism of the action of organic nitrates and inorganic nitrites in hypertension has been recently elucidated.*

EARLY DIAGNOSIS OF POLIOMYELITIS

JOHN F. POHL, M.D.
Minneapolis

Treatment of poliomyelitis should begin as soon as possible after the onset of the disease in order to relieve the discomfort of patients and to minimize crippling. An analysis of 1,125 cases of poliomyelitis treated in Minneapolis during the 1946 epidemic reveals that the symptoms and observations are sufficiently characteristic to enable the diagnosis to be established in most patients within twenty-four hours of the onset. The study also discloses that paralysis is not a useful diagnostic sign because paralysis or weakness of the muscles is not a common early event and in a considerable number of cases does not occur at all. To await the appearance of paralysis to confirm the diagnosis or to begin treatment is inadvisable. It is now recognized, but should be emphasized, that patients without paralysis are often seriously ill and may become crippled from conditions other than paralysis which affect the muscles. All cases should be brought under treatment as soon as possible.

While it is known that the disease varies in the intensity of its attack the early medical symptoms are common to all types of cases including those which do not at any stage show evidence of weakness of the muscles. In this series of 1,125 cases 65.4 per cent (736 cases) progressed to paralysis of some degree but 34.6 per cent (389 cases) did not show paralysis at any time. The mortality was 6 per cent (68 patients), indicating that the epidemic was of average severity and that the observations drawn from the study of these cases are representative of the disease.

EARLY SYMPTOMS

Headache was the most distinctive initial complaint denoting the onset of poliomyelitis. This was usually of a severe, generalized, unrelenting type, which is rare in the illnesses of childhood. Headache was a particularly prominent symptom in 57 per cent of all the patients in this series during the first twenty-four hours of the disease.

Fever was noted early in the disease, but fever is not distinctive as a symptom. In this series fever was recorded in 80 per cent of the patients within the first twenty-four hours of the illness. The elevation of temperature in poliomyelitis is usually moderate and is seldom observed to rise above 103 F.

In addition to headache and fever the principal symptoms of the disease (in the order of frequency of occurrence during the first twenty-four hours) were nausea, vomiting, anorexia, stiff neck, stiff back, painful extremities and general malaise with listlessness.

It has been stated frequently that the early symptoms of poliomyelitis may be indistinguishable from those of the more ordinary diseases affecting the nose, throat and respiratory system. Although 4 per cent of the patients in this series complained of head cold or respiratory infection attributed to the onset of the disease, the complaint was not generally confirmed on physical examination.

Sore throat or tonsillitis was an early complaint in 10 per cent of the patients, but inflammation was not found to be present in the physician's examination of these patients. The absence of inflammation of the throat in patients who complain of sore throat suggests the important possibility that the lesion is a "painful throat" of neuritic origin. The complaint of sore throat occurred ten times more frequently in the cases in which bulbar symptoms ultimately developed than in those which eventually showed paralysis of spinal origin. The inference to be drawn is that patients complaining of sore throat should be watched closely for evidence of bulbar paralysis.

A feature of poliomyelitis which may result in unnecessary delay unless kept in mind is the tendency in some cases for the symptoms to abate temporarily after an initial illness which usually lasts twenty-four hours. This type of history was obtained in 22 per cent of the cases in this series. Scrutiny of the histories of these patients reveals that the early symptoms were definite and recognizable. The significance of the recurrence of symptoms after a remission of two to three days was not apparent and did not seem related to the onset of paralysis. The interval or recurrent type of onset was present in 17 per cent of the patients in whom paralysis never developed. An opportunity was afforded to study 39 patients admitted to one hospital unit on the day of onset of the disease. None of these patients who were hospitalized early showed the phenomenon of recession and recurrence of symptoms, although in several paralysis developed after admission to the hospital.

PHYSICAL EXAMINATION

The diagnosis of poliomyelitis can be established with a high degree of certainty by physical examination. The typical patient lies quietly in bed and does not wish to be disturbed. There is a singular irritability and resentment against being moved or handled. The painful sensitivity of the peripheral tissues indicates the presence of spasm, a common and useful observation for the purpose of diagnosis early in the disease. Stiff neck, stiff back and shortened hamstrings are familiar examples of symptoms caused by the disease, but muscles elsewhere in the body may also be involved by spasm, including those which are not attached to the spine. The disorder occurs in the nonparalytic as well as the paralytic case.

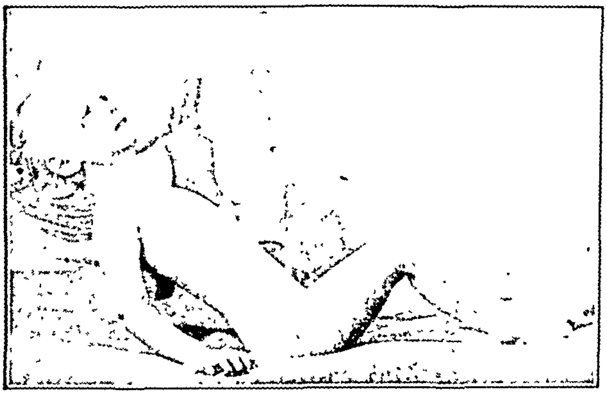
From the Elizabeth Kenny Institute, Minneapolis.

For examination the patient is placed supine on a firm bed or table. On placing the hand beneath the head and attempting to flex the neck resistance will almost invariably be encountered as early as clinical symptoms have occurred. An attempt to flex the body will disclose stiffness of the back. When the trunk is flexed the knees will rise from the bed because of shortness of the hamstring muscles, as shown in the accompanying illustration. The stiffness is due to the condition of spasm in the posterior muscles. On search, the same hypertonicity and shortening may be found, although less frequently, in other muscles of the body and in all types of cases (table 1).

The patient may complain of pain in the muscles involved by spasm, or pain may be elicited by gently stretching the affected muscles.

When the condition affects the muscles of any part of the respiratory mechanism the breathing of the patient may be impaired. Spasm may affect the abdominal muscles and simulate the spasm of acute appendicitis.

It will be noted from table 2 that spasm occurs more frequently in the paralytic than in the nonparalytic type of case. Experience with this group of patients has shown that spasm is severer in the paralytic than in the nonparalytic case and is more difficult to relieve. In this series of cases (1,057 surviving) it was necessary to treat the nonparalytic patients (389) for an average of twenty-three days before the spasm was relieved, whereas from two to ten months (depending on its severity) was required to relieve the spasm in the paralytic cases (668).



Typical patient with poliomyelitis in the acute stage showing examination for spasm in the posterior muscles.

PARALYSIS IN DIAGNOSIS

Paralysis or weakness of the muscles is easily discoverable when it occurs in poliomyelitis, but the value of this observation for the purpose of diagnosis is diminished by the fact that paralysis is not a common early condition and may not occur at all.

There was no detectable evidence of weakness or paralysis at any time in 389, or 34.6 per cent, of the 1,125 cases in this series. Paralysis occurred at some time within fifteen days of onset in 736, or 65.4 per cent, of the patients.

None of the patients complained of weakness or paralysis as an initial symptom, and this condition appeared during the first twenty-four hours in only 5 per cent of the cases (table 3). In 11.7 per cent of the patients the date of development of paralysis could not be determined from case records; but granting that these might have occurred within the first few days of illness, paralysis would still not be considered a common early symptom. It will be noted from table 3 that in 9.6 per cent of the patients paralysis did not occur until after the disease had been in progress for more than seven days.

Table 1.—*Frequency of Occurrence of Spasm on the Basis of Clinical Examination of the Total Surviving (1,057) Cases of Acute Poliomyelitis*

Muscle in Spasm	Occurrences No. of Cases	 % of Total Cases
Posterior neck	1,057	100.0
Posterior spinal	1,057	100.0
Hamstrings	1,057	100.0
Calf	846	80.0
Tensor fasciae femoris	560	53.0
Upper trapezius	220	20.8
Plantar fascia	153	14.5
Quadriceps femoris	103	9.7
Pectoralis major	98	9.3
Quadratus lumborum	70	6.6

The finger flexors, arm adductors, abdominals and biceps brachii were involved to the extent of 2 per cent of the cases and other muscles to a lesser extent.

Patients who manifested bulbar symptoms, such as difficulty in swallowing, nasal regurgitation, facial weakness, nasality and difficulty in speech, gave evidence of muscular dysfunction, on the average, slightly earlier than did patients in whom the spinal type of paralysis developed (table 4).

EXAMINATION OF THE SPINAL FLUID

The spinal fluid should be examined in every suspected case as an aid not only in confirming the diagnosis but in quickly separating out other diseases. The typical spinal fluid of poliomyelitis has the following characteristics:

✓ Crystal clear.
Pressure normal or low.
Protein slightly elevated or normal.
Cell count moderately elevated, usually not above 350 per cubic millimeter. (Cell counts were not elevated in 4 per cent of the cases in this series in which other observations served as the basis of diagnosis. The cell count was normal in 1 per cent of the patients in whom paralysis occurred.)

Table 2.—*Occurrence of Spasm on the Basis of Clinical Examination of Paralytic and Nonparalytic Types of Acute Cases of Poliomyelitis (1,057 Total Living Cases)*

	Occurrence of Spasm			
	668 Paralytic Cases		389 Nonparalytic Cases	
Muscle in Spasm	No. of Cases	% of Cases	No. of Cases	% of Cases
Posterior neck	668	100.0	389	100.0
Posterior spinal	668	100.0	389	100.0
Hamstrings	668	100.0	389	100.0
Calf	556	83.4	290	74.6
Tensor fasciae femoris	374	56.0	186	47.9
Upper trapezius	173	25.9	47	12.1
Plantar fascia	124	18.6	29	7.5
Quadriceps femoris	93	13.9	10	2.6
Pectoralis major	95	14.2	3	0.8
Quadratus lumborum	55	8.2	15	3.9

The polymorphonuclear cells frequently predominate during the first forty-eight hours of the disease, after which time the majority of the cells are usually of the mononuclear variety.

Other of the usual laboratory studies of the spinal fluid or blood have not yet proved useful, as no changes have so far been disclosed which are particularly distinctive of poliomyelitis. Such examinations, however, are helpful in establishing a discriminative diagnosis in suspected cases which are under observation.

DIFFERENTIAL DIAGNOSIS

The diseases affecting the nervous system which are commonly confused with poliomyelitis are Guillain-Barré, encephalitis, meningitis and transverse myelitis. Guillain-Barré disease is noteworthy in contradistinction to poliomyelitis for the absence of stiffness of the neck and for the tendency of weakness or paralysis to progress over a period of weeks. The spinal fluid typically shows a high protein content without an increased cell count.

The patient with meningitis or encephalitis is usually restless and hyperactive at the onset in comparison with the listlessness and lethargy of the poliomyelitis patient. Transverse myelitis is marked by sensory changes, most unusual in poliomyelitis, in addition to the weakness.

Table 3.—*Occurrence of Paralysis in 1,125 Cases of Acute Poliomyelitis*

Day of Occurrence	No. of Cases	% of Cases
First	56	4.9
Second	82	7.3
Third	119	10.7
Fourth	89	7.9
Fifth	59	5.2
Sixth	52	4.6
Seventh	40	3.5
Eighth through fifteenth	108	9.6
Undetermined *	131	11.7
Total	736	65.4
Total paralytic cases	736	65.4
Total nonparalytic cases	389	34.6
Total cases	1,125	100.0

* The day of onset of paralysis was not known in 131 paralytic cases including the 68 deaths.

Table 4.—*Occurrence of Paralysis in Spinal and Bulbar Types of 605 * Acute Cases of Poliomyelitis*

	First Appearance of Paralysis			
	431 Spinal Cases		174 Bulbar Cases	
Day of Occurrence	No. of Cases	% of Cases	No. of Cases	% of Cases
First	37	8.5	19	11.0
Second	56	13.0	26	15.0
Third	81	18.7	38	21.8
Fourth	61	14.3	28	16.1
Fifth	41	9.5	18	10.3
Sixth	38	8.8	14	8.0
Seventh	31	7.2	9	5.2
Eighth through fifteenth	86	20.0	22	12.6
Total	431	100.0	174	100.0

* The day of onset of paralysis was not known in 131 paralytic cases including the 68 deaths.

CONCLUSION

In the acute stage of poliomyelitis the principal manifestations in the peripheral structures which are of use in diagnosis are spasm (shortening of the muscles) and paralysis (or weakness of the muscles). Spasm appears early and is present in every case. Paralysis is easily discoverable when it occurs, but it is not a common early observation and does not appear at all in a considerable number of cases. Spasm is generally severer in the paralytic patient; the longer it is untreated the more difficult it is to relieve. In order to aid the prevention of contractures and deformities from spasm it is advisable to begin treatment to the peripheral tissues before weakness or paralysis has occurred. No delay in treatment is prudent once the diagnosis has been established.

OCULOGLANDULAR TULAREMIA TREATED WITH STREPTOMYCIN

PERCY MINDEN, M.D.
Beverly Hills, Calif.
and
J. E. SPRINGER, M.D.
Akron, Ohio

Lesions resembling oculoglandular tularemia were first noted by Martin[1] in 1907. He described 3 cases of conjunctivitis in patients with what he called "rabbit fever." It was not until 1911, however, that the causative organism was first isolated by McCoy and Chapin,[2] who were investigating a disease of ground squirrels in Tulare county, California. The organism was named Bacillus tularense after the county where it was first discovered. Fourteen years later one of Martin's patients was found to have a positive agglutination test for tularemia.[1] In 1913 Vail[3] saw an unusual form of conjunctivitis and Wherry and Lamb,[4] working on this case, were the first to isolate Bacterium tularense in pure culture from a human being.

At first it was thought that rabbits alone were responsible for transmitting this disease to man, but it has since been shown that many rodents, rabbit ticks, wood ticks, deer flies, coyotes, hogs, quail, pheasants and other animals and birds are hosts and transmitters of this infection to man.[5]

After the discovery of a causative organism tularemia began to be recognized in many parts of the United States, Canada and Europe. Francis reviewed 679 cases in 1928,[6] and he classified them in four main groups, as follows: (1) the ulceroglandular form, occurring most frequently and characterized by an open ulceration, regional lymphadenopathy and severe systemic manifestations out of proportion to the local lesion; (2) the glandular form characterized by regional lymphadenopathy in which a primary lesion is not evident; (3) the typhoid form in which both a primary lesion and lymphadenopathy are absent but in which constitutional symptoms predominate, and (4) the oculoglandular form in which the primary lesion is a conjunctivitis. In this series 32 cases, or 4.7 per cent, were of the oculoglandular form.

In 1939 Oosting[7] noted that there had been 68 cases of oculoglandular tularemia recorded up to that time, and he reported another. In 1940 Foshay[8] reported 600 cases of all forms of tularemia, of which 11, or 1.8 per cent, were of the oculoglandular form. In his series the primary lesion was found in the conjunctiva less often than in any other location. Francis[9] reported 78 cases in the United States and 18 in foreign countries up to 1940. Since then 8 cases have been reported in the

literature by Thompson and Glynn,[10] Gorrell,[11] Last,[12] Guerry[13] and Siniscal.[14] These and our own case bring to a total of 87 the recorded instances of oculoglandular tularemia in the United States. Undoubtedly many others have not been reported and many more have gone unrecognized. Nevertheless this small number serves to emphasize how unusual this manifestation of tularemia is.

SYMPTOMATOLOGY

Symptoms may come on quickly after an incubation period of two to five days. First the eyelids begin to swell, and then the preauricular, the submaxillary, the anterior cervical lymph glands and, sometimes, the axillary nodes become decidedly swollen and tender. As a rule, one eye alone is involved. On everting the eyelid, a pronounced degree of inflammation of the conjunctiva is seen, usually confined to the lower lid. Scattered through the red conjunctiva are small yellow nodules. These soon break down and leave shallow yellow ulcers, which stand out in well defined contrast to their scarlet background. The number of ulcers varies from one to ten, averaging about six. The cornea is involved only in the severer cases. With the appearance of the ocular lesions, constitutional symptoms become decided. Fever, chills, severe sweats and general malaise and weakness are the rule.

In a series reported by Vail in 1929[1] the ocular symptoms lasted about four weeks, the febrile reaction one to six months and general weakness of an incapacitating nature for six months or longer. The neighboring lymph glands remained large for many months after the primary lesion had disappeared. Francis[6] reviewed a large number of cases of all forms of tularemia and found that there was complete weakness for one month, weakness on moderate exertion during the second month and ability to do half time work during the third month of the disease. Many patients did not return to normal strength for six to twelve months. During convalescence there may be recurrent attacks of fever, sweats, attacks of extreme weakness and recurrent glandular enlargement. These recurrences may themselves last six to twelve weeks. All workers comment on the extraordinary variability of this disease, the source of infection, the modes of transmission and the clinical manifestations.

DIAGNOSIS

In his excellent review Francis[6] has emphasized four points that should lead to the diagnosis of tularemia: (1) a history of having dressed or dissected a wild rabbit, or of being bitten by a tick or a fly; (2) a primary lesion, such as a papule, a persistent ulcer or a primary conjunctivitis, followed by conjunctival ulceration; (3) persistent enlargement of the neighboring lymph glands, and, (4) fever of two or three weeks' duration.

The diagnosis may be confirmed by an agglutination test of the patient's serum. The reliability of this test is almost absolute. Its use makes diagnosis possible with a degree of accuracy seldom found in medical practice. Agglutinins are usually absent until some time during the second week. There follows an abrupt rise in titer during the third week, reaching a maximum from the fourth to the seventh week. The titer then gradually falls, and agglutinins may remain in low concentrations indefinitely. Human tularemia serums may also cross agglutinate Brucella abortus and Brucella melitensis organisms. In such cases the titer of the latter organisms will be less than the titer of Pasteurella tularensis. Isolation of the organisms from the conjunctiva or from the blood is difficult and requires specially enriched mediums and animal inoculation. For early diagnosis there is available a bacterial suspension intradermal test, which becomes positive during the first week.[15]

COMPLICATIONS

Complications are unusual in this disease. Those most likely to occur are ulcerative and suppurative adenitis, ulceration of the cornea and acute, purulent dacryocystitis. Francis has reported a case of ulceration with perforation of the ocular conjunctiva followed by prolapse of the iris.[6]

MORTALITY

In 1936 Pessin[16] reported the general mortality of tularemia to be 4.8 per cent in 5,426 cases. Francis[6] found a mortality of 6.9 per cent in 15,525 cases of all types of tularemia, with a mortality of 9 per cent in 78 cases of oculoglandular tularemia.

TREATMENT

Many methods of treatment have been tried. The most effective of all has been treatment with serum, developed by Foshay.[8] Even here, however, the high morbidity rate leaves much to be desired. The sulfonamide compounds, arsenic compounds, iodides, metaphen, acriflavine and penicillin have all been used without benefit.[17] Zeiter[18] and Siniscal[14] reported comparatively favorable results with the use of fever therapy on a few patients. Jackson[19] has reported favorably on the use of a solution of bismuth tartrate intravenously.

In 1944 Heilman's[20] experiments showed that the antibiotic substance streptomycin possessed considerable activity against Past. tularensis, as measured by in vitro and in vivo experiments. Lethal infections were established in mice, all of whom recovered when treated with streptomycin. Control animals failed to recover from the disease.

These experiments led to the use of streptomycin in the treatment of tularemia in human beings. Foshay and Pasternack[21] described 7 cases with early favorable results in all. None of these patients, however, had the oculoglandular form of tularemia. The experiences of Foshay and Pasternack compared favorably with previous results when serum therapy was used. Abel[22] has also reported on the effectiveness of streptomycin in 3 cases.

The case of the oculoglandular type of tularemia reported here is of interest both because of its comparative rarity and because there has been no report up to the time of writing of the treatment of this disease with streptomycin.

REPORT OF A CASE

History.—A white boy aged 11 was hospitalized June 8, 1946, with swelling of his right eye of eight days' duration. Nine days previously his right eye had been struck by a stone. There was apparently no injury, as the incident was forgotten and he went in swimming later that day. The next day he complained of something in his eye, and the lids became swollen and reddened. His mother used eye washes of boric acid, and all discomfort disappeared. Seven days before admission, fever was noted. This persisted daily and was worse in the late afternoons than in the mornings. There were no chills, but there were severe sweats. The boy was kept in bed and except for mild generalized weakness and malaise had no complaints. The swelling about his eye gradually increased during this time. Family and past histories were noncontributory.

Physical Examination.—On admission the patient appeared to be a well developed and well nourished white boy, of good color and not in acute distress. The temperature by rectum was 104 F., the pulse rate was 100 and the respiratory rate 18. There was decided swelling and tenderness of the right eye. Both lids were edematous, and the palpebral conjunctivas were red and inflamed. On the lower right palpebral conjunctiva were scattered six small shallow irregular ulcers with yellowish bases. The bulbar conjunctiva appeared normal. The pupils were round, regular and equal and reacted to light and accommodation. The left eye appeared normal.

Examination of the ears, nose and throat revealed nothing except a mild pharyngitis. The chest was normal in appearance, size and shape. Resonance and breath sounds were normal, and adventitious sounds were not noted. Physical examination of the heart revealed no abnormality. The abdominal wall was soft, and there was no tenderness or rigidity. The spleen and liver were not palpated, nor were any other abdominal organs or masses palpable. The nervous system was normal. Skin and tendon reflexes were present and equal, and there was no evidence of meningeal irritation. The cranial nerves were normal.

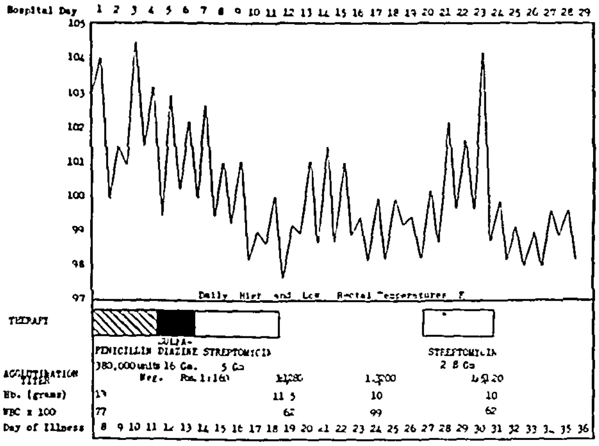
The right preauricular and submaxillary lymph glands were grossly enlarged and tender. All the lymph glands of the right anterior cervical group were likewise abnormally enlarged. Two large nodes were palpated in the right axilla. Throughout the rest of the body the lymph glands were normal in size and consistency.

Laboratory Examination.—Examination of the blood revealed a white cell count of 7,700, with 79 per cent polymorphonuclear leukocytes, 19 per cent lymphocytes and 2 per cent monocytes. The red cell count was 4,250,000, with a hemoglobin level of 13 Gm. per hundred cubic centimeters (Haden). Urinalysis, Kahn and Kline tests, and tuberculin tests were negative. Blood culture and culture from material on the palpebral conjunctiva were negative. These were planted only on routine mediums.

Course.—Penicillin therapy, 20,000 units at three hour intervals intramuscularly, was commenced. After three days the eye appeared to be worse. New conjunctival ulcers were forming, and the ocular conjunctiva was becoming involved. Further inquiry revealed that sixteen days before admission, while he was playing in the woods with another boy, our patient had found a dead rabbit. He handled the rabbit and carried it for a short distance. Later he was a close and interested bystander while his older playmate proceeded to dissect the animal. His playmate was wearing gloves at the time. The incident had already been forgotten and, of course, had not been considered significant by the parents.

With this knowledge, serum agglutination tests for tularemia, undulant fever and typhoid were commenced, and penicillin therapy was discontinued. Sulfadiazine therapy was initiated. The following day all agglutination tests were negative, but it was nevertheless felt that our patient did present the clinical picture of oculoglandular tularemia. A request for streptomycin was made to Dr. Chester S. Keefer, who generously arranged to have a supply sent to us. Before the streptomycin arrived no appreciable effect of therapy with sulfadiazine was noted. Streptomycin therapy was started late on the sixth hospital day and the drug was administered as directed, 1 Gm. daily dissolved in isotonic sodium chloride solution and given in divided doses every three hours intramuscularly for five days (1,000,000 units daily divided into eight doses of 125,000 units each). We were gratified to find that an agglutination test for tularemia was now positive in a dilution of 1 : 160, confirming our diagnosis.

The clinical response to therapy with streptomycin was striking. After twenty-four hours the edema was less and all tenderness had disappeared from the eye and regional lymph glands. As seen in the accompanying chart, the temperature began to fall after twenty-four hours, reaching a normal level on the fourth day of therapy. After forty-eight hours the ocular conjunctiva had considerably improved, and swelling about the face and regional lymph glands was much reduced. Improvement proceeded so that after five days of therapy the only remaining evidence of disease was a mild palpebral conjunctivitis and small palpable lymph glands in the anterior cervical, axillary and preauricular groups.



Clinical course of boy aged 11, weighing 32.7 Kg., admitted to hospital June 8, 1946 with oculoglandular tularemia and discharged July 6, 1946

A serum agglutination test for tularemia at this time was positive in a 1 : 1,280 dilution. The agglutination for Br. abortus was positive in a 1 : 40 dilution. Throughout the treatment period the patient was observed for possible toxic effects of streptomycin, but untoward effects were not noted.

After streptomycin therapy was discontinued there began again a gradual daily rise in temperature to levels of 100 and 101 F. The general condition of the patient and the local appearance of the conjunctiva remained good and except for fever there was no sign of illness or disability. In order to forestall a long-drawn-out convalescence, a second lot of streptomycin was generously sent to us from another company, and treatment was started again on the twentieth day. The dosage and method of administration was the same as with the first course. This time, however, there was much pain and tenderness at the sites of injection, and on the twenty-first day the temperature rose to 102.4 F. This continued until the twenty-second and twenty-third days, when the temperature was 104 F. The administration of streptomycin was discontinued, since there was no other apparent cause for this fever, and the temperature immediately returned to normal and remained so for six days, after which our patient was discharged from the hospital. No other untoward effects that could be attributed to the drug were noted. At this time physical examination revealed an eye that was normal in all respects and a boy whose color was good and who was full of pep and energy, revealing no evidence of weakness or tiredness.

---

[22] Abel, O., Jr.: The Use of Streptomycin in Tularemia, J. Missouri M. A. 43: 167 (March) 1946.

During the last few weeks in the hospital a gradually rising agglutination titer was observed. On the seventeenth hospital day, it was 1:3,200 for Past. tularensis and 1:80 for Br. abortus. On the twenty-fourth day it was 1:5,120 for Past. tularensis and 1:80 for Br. abortus. Shortly before discharge the hemoglobin content of his blood had fallen to 10 Gm. per hundred cubic centimeters, and the red blood cell count was 3,530,000. Examination of the blood revealed otherwise normal conditions.

Following discharge the boy was observed again at intervals during the next three months. His eye and his general condition remained normal during this period.

COMMENT

The first course of streptomycin produced gratifying results. This was similar to the observations of others.[23] The early relapse in our patient was not accompanied by the usual constitutional symptoms. He appeared and felt perfectly well during the entire febrile period. There was, in fact, difficulty in keeping him in bed and in persuading his parents that he was not well. The sharp sudden rise in temperature which accompanied the second course of treatment and its immediate subsidence after the drug was discontinued can evidently be attributed to the streptomycin rather than to the disease process. Either the second lot of streptomycin received was not as pure a product as the first or the patient had by this time become sensitized to the drug. The latter seems likely, since an apparent sensitization to streptomycin with violent febrile reactions during a second course of therapy has also been observed by Hinshaw and Feldman.[24]

There was no question in our minds, however, that the first course of therapy was responsible for rapid improvement in the primary lesion, the fever and the constitutional symptoms. The absence of fever during the patient's convalescence must also be attributed to the effect of streptomycin therapy.

In evaluating the effects of serum therapy, Foshay found that in 518 untreated cases, the average duration of disease was 3.8 months, the average disability was 3.36 months, fever 31.59 days and duration of the primary lesion 39.48 days. In our patient the duration of disease was 30 days, fever 30 days and the primary lesion 17 days. These figures compare favorably with those for untreated cases, as well as with Foshay's figures for 600 patients who received specific serum therapy.[8] On this basis at least it appears that streptomycin did favorably alter the expected course of the disease in our patient.

It is quite apparent that streptomycin has been in use for too short a period to properly evaluate its effectiveness in the treatment of human tularemia. Every indication at the present time suggests that it is a decided improvement over other forms of therapy. Future investigation may alter present methods of administration and dosage and improve further the therapeutic effect of the drug. It is certainly desirable to observe the results of more intensive and prolonged therapy in large numbers of patients before forming definite conclusions as to what results may ultimately be expected in the treatment of a disease that is naturally so variable.

SUMMARY AND CONCLUSIONS

A case of oculoglandular tularemia is presented together with a brief review of the literature. This is an unusual manifestation of tularemia and probably the first to be treated with streptomycin. There was immediate and dramatic improvement of the primary lesion, constitutional symptoms and fever, but the general course of the disease, as manifested by a return of low grade fever, was prolonged for thirty days. During convalescence a second course of streptomycin brought about symptoms which probably represented either sensitivity of our patient to streptomycin or an impurity in the drug. The course of the disease was shorter in all respects than that of the average untreated case.

IMMUNIZATION PROCEDURES IN PEDIATRICS

JOHN J. MILLER Jr., M.D.
San Francisco

It is the purpose of this paper to recommend certain preparations for active immunization against smallpox, diphtheria, tetanus and pertussis. These procedures have universal application to the practice of pediatrics. Active immunization against typhoid fever and scarlet fever will not be discussed in as much as it is necessary or advisable only within certain geographic limits. The recommendations made here are based on a review of the literature[1] biased, no doubt, by my own experience in pediatric immunity clinics. I will also briefly summarize results of a study of combined immunization with a mixture of diphtheria and tetanus toxoid containing Hemophilus pertussis vaccine.

SMALLPOX

Calf lymph virus has yet to be excelled as the preparation of choice for vaccination against smallpox. Failures are due to nonpotent lymph. The preservation of the vaccine at temperatures below 50 F. at all times and preferably in an electric refrigerator is essential to the maintenance of potency. Vaccination should always be on the arm or between the shoulder blades. Secondary infections are more likely to occur on the leg. The multiple pressure method should be used. A light sterile gauze dressing loosely applied is desirable to prevent fingernails from contact with the area. Vaccination may be performed at any time during the first year of life. During the first four months, however, occasional refractory persons are met with. Eczema is a positive contraindication. Revaccination should be done when the child starts to school.

From the Department of Pediatrics, Stanford University School of Medicine.

DIPHTHERIA

Fortunately in this country there have not been any epidemics of malignant diphtheria. This being so the various types of diphtheria toxoid used in this country have not been subjected to the crucial test. In judging the products available one can only rely on tests of immunity.

Immunity in diphtheria is primarily antitoxic. It is the sum of existing circulating antitoxin and the capacity to manufacture more antitoxin rapidly on the slightest secondary stimulus. Existing circulating antitoxin can be measured by neutralization tests in laboratory animals. Capacity to react can be measured by a second determination after a reinjection. The Schick test not only measures the amount of antitoxin available at the site of injection but also the reactive capacity. For example, in previously immunized persons the injected Schick toxin may stimulate antitoxin rapidly enough to partially neutralize itself before injury occurs to the tissues and erythema results.[2] A Schick test thus serves incidentally as a small booster injection. Even though reports of malignant diphtheria in Schick-negative persons are now coming in, they are the exception rather than the rule. Comparison of antigens by means of the Schick conversion rate is valid. Furthermore, in the individual case in private practice the Schick test enables one to pick up the occasional poor reactor, provided that the test is performed more than three months after immunization.

Basic immunization should be performed during the first two years of life and, to be conservative, probably not before the eighth month, though recent evidence suggests that younger infants can be immunized. There is incontrovertible evidence, provided by the classic studies of Volk and Bunney,[3] that two injections of alum precipitated diphtheria toxoid provide a basic immunity slightly higher in degree and of longer duration than do three injections of fluid toxoid. The argument against alum precipitated toxoids, namely, the occasional formation of sterile abscess, has been practically nullified by improvement in the product. The injections should be given deeply and, in my opinion, intramuscularly, as Bousfield advises.[4] The interval between the injections should be one to three months. In the presence of an epidemic, this may be shortened to three weeks.

Fluid toxoid, three injections at monthly intervals, is second best and, as such, is not the agent of choice, at least in primary immunization. Fluid toxoid, however, is preferable in older age groups.[5] It should be used in exceedingly small doses, or suitably diluted, in those children who are sensitive to diphtheria bacillary protein. Sensitivity is determined by the intradermal injection of a 1 : 100 dilution of fluid toxoid. This test, known as the Moloney test,[6] is essential before primary or secondary immunization in persons 10 years of age or more. (I hope Dr. Thelander will discuss immunization in the older age groups from her large experience.)

There remains to be mentioned aluminum hydroxide adsorbed diphtheria toxoid. This has been used for years abroad.[7] In the remote community of Iceland, where only 10 per cent of the children under 13 years of age were naturally Schick negative, Sigurjonsson obtained 96 per cent Schick negative reactions seven months after two injections of this product at a three week interval. Four years later 74 per cent were still Schick negative. This is rather remarkable. In my own experience with aluminum hydroxide adsorbed toxoid, during the past four years at Stanford, I have yet to observe an injected child with a positive Schick test.

A fourth type of diphtheria toxoid, protamine-precipitated toxoid, has been reported recently. Antitoxin titers in a large group of children were unusually high.[8]

In conclusion, then, for basic immunity the conservative pediatrician should stand by alum precipitated toxoid. The more experimentally minded may with justification use the aluminum hydroxide adsorbed product.

When the child is 5 or 6 years of age and ready for kindergarten or school, should one perform a Schick test or simply give a booster injection? The public health physicians are warranted in omitting the Schick test and giving one reimmunizing injection.[9] In private practice, however, it is my belief that one should perform a Schick test, controlling it with a 1 : 100 dilution of toxoid.[10] If the test is negative, one need do no more. The toxin, and especially the diluted toxoid have served as little boosters. If the test is positive, two reinjections of alum precipitated toxoid should be given. The diluted toxoid control will have identified the few persons sensitive to diphtheria protein and thus enable the physician to proceed cautiously with reinjections.

TETANUS

Immunization against tetanus is quite a different problem from that against diphtheria. There are no naturally immune persons. Tetanus antitoxin has never been detected in nonimmunized men, except in China,[11] nor has it been found even after recovery from clinical tetanus.[12] Although tetanus spores are ubiquitous, they are of course not antigenic and, unlike the diphtheria bacilli in the street cars, they cannot restimulate the immunity mechanism. Only the toxin produced by the bacillary forms under anaerobic conditions is antigenic and then but feebly so.[13] Boyd [14] has attributed the 22 cases of tetanus which occurred in the immunized British forces to an inadequate level of circulating antitoxin.

The aim in tetanus immunization, then, is to attain and maintain the highest degree of immunity at all times. After studying the initial lesions in 56 cases of clinical tetanus in children, Pratt[15] concluded that reduction in the incidence of this disease can only be accomplished if this aim is kept in view. The majority of his cases resulted from trauma or infection so trivial that they were overlooked either by the child himself, his parents or his physician. It is not plausible to expect parents to bring children into the office for a booster injection after each scratch. Antitoxic immunity, of itself protective without reliance on restimulation, is therefore the goal.

A great deal of evidence[16] has accumulated to indicate that alum precipitated tetanus toxoid produces a more durable immunity than plain or fluid toxoid. Two injections are usually advised, but three injections[17] are preferable. The interval should be three months. The first two injections may be combined with diphtheria toxoid. With this dosage the great majority of children will produce and maintain more than 0.1 unit of tetanus antitoxin per cubic centimeter of serum for one year. One tenth of a unit of tetanus antitoxin is believed to be protective of itself against such toxin as may be produced in trivial wounds.

Aluminum hydroxide adsorbed tetanus toxoid, alone or in combination with other antigens, may in the future equal or surpass the alum precipitated product as the agent of choice. Local reactions are less frequently encountered. Antitoxin levels produced are high and remarkably well maintained.[18]

A booster injection of 0.5 cc. alum precipitated tetanus toxoid should always be given one year after completion of the basic course. Thereafter reinjections should be repeated every two years. Annual reinjections with 0.25 cc. are more easily remembered. They can be given regularly at the time of the child's annual physical examination.

This schedule for immunization of course will be interrupted if the child is brought in to the office with an abrasion or anything more serious. A booster injection should then be given immediately. As 1 cc. fluid toxoid will raise the child's antitoxin titer more promptly than alum precipitated toxoid,[19] it is here the agent of choice. The minimum recorded incubation period of tetanus is as short as two days,[14] but incubation periods of less than seven days are rare. A booster injection cannot be expected to be of any value against such fulminating intoxication. The level of circulating antitoxin resulting from the child's previous injections of toxoid will be decisive. This level, however, can be temporarily increased by administering tetanus antitoxin (horse serum). In fact, resort to this old procedure is indicated, by no means contraindicated, in cases with extensive contaminated wounds. The recall injection of toxoid is injected *simultaneously* into another extremity.

PERTUSSIS

The effectiveness of active immunization against pertussis has been proved by numerous studies in the field.[20] Occasional unfavorable reports can be accounted for by the use of nonpotent lots of vaccine. There is yet no United States standard of potency because there is no officially accepted means of assaying potency. Soon this may be remedied. Until then occasional nonpotent lots of vaccine may continue to appear from the best available sources. However, it must be admitted at once that in pertussis vaccine one does not have as almost universally potent an antigen as is available in either diphtheria or tetanus toxoid. Speaking conservatively, the total mass of evidence from field studies in different parts of the country indicates that H. pertussis vaccine will completely protect 2 of 3 children exposed in the family and 4 of 5 children exposed less intensely outside the home. Those vaccinated children who do contract pertussis usually have milder attacks and rarely die. Some apparent failures of immunization in vaccinated children are due to infections with the Bacillus parapertussis.[21] These infections will seldom be diagnosed correctly, as the cough is clinically indistinguishable from that of pertussis: in other words they are cases of whooping cough but not of pertussis.

The protective value of H. pertussis vaccines was proved in the field with simple saline suspensions of bacilli in the antigenic phase 1. All freshly isolated strains are in phase 1. Unless special precautions are taken, stock cultures will change into relatively nonantigenic phases. When saline suspensions are used the total number of bacterial cells injected should be at least 70 billion. Ninety to 120 billion cells are better. This total dose is divided into three injections and given preferably at three or four week intervals.[22] One week intervals, however, should be used during an epidemic. Suspensions containing 15 and 20 billion cells per cubic centimeter are, in my experience, less likely to provoke local reactions than more concentrated suspensions.

Again, as with the toxoids, an alum precipitated product is to be considered. Field studies and serologic evidence[23] indicate that 30 or 40 billion H. pertussis in the presence of alum are as effective as 80 to 100 billion bacterial cells in saline solution. Three injections of a fraction of a cubic centimeter each are given at monthly intervals. In my opinion, however, the superiority of the alum precipitated vaccine has not been demonstrated in the age groups customarily immunized—that is, in infants aged 5 months or older. Unless combined immunization with alum precipitated toxoids, that is, a mixture, is to be used, I prefer to give the vaccine in saline solution in order to minimize local reactions.

This brings up the question of how early in life an infant can be actively immunized. Using an alum precipitated vaccine, Sako and his co-workers[24] in New Orleans conclusively demonstrated that injections begun between 1 and 2 months of age and repeated twice at monthly intervals (total dose 40 billion organisms), protected 81 per cent of infants against familial exposure. More important, none of their immunized infants who were attacked died This well controlled field study was extremely important in that it opened the way for trials of active immunization during earliest infancy. Now, not only immunization against pertussis but against typhoid, diphtheria and tetanus is being attempted at an age at which it was formerly believed that the immunity mechanism was undeveloped. The evidence available[25] suggests that plain vaccine may possibly be less effective than alum precipitated vaccine in infants under 3 months of age

There are on the market soluble antigens and endotoxoids of H. pertussis. The available evidence[26] indicates that they are of little or no prophylactic value. Only suspensions of whole cells in saline solution or with some adsorbent like alum should be used.

Complete protection against pertussis of ten years' duration may result in some persons from the primary course of immunization. Reinjections of vaccine, however, should be the rule. Whenever the child is known to have been intimately exposed a stimulating dose of 20 billion cells should be given.[27] Otherwise, in my experience, two reinjections with this dose (20 billion), the first about a year after the basic course and the second at the age of 6 years, are sufficient.

MIXED TOXOIDS AND VACCINES

It is apparent that if it is necessary to employ all the immunizing procedures to which I have alluded, the children's arms will resemble pin cushions. Mixtures of antigens will save the physician's time and the child's extremities, not to mention his tears. Ramon[28] challenged the classic German concept of "competition of antigens" and demonstrated clearly that mixtures of bacterial vaccines and toxoids might be used. Furthermore, he showed that the immune response to the toxoids, that is, antitoxin production, was potentiated thereby. Such multiple antigens, usually incorporating typhoid vaccine, have been employed by the French Public Health officials for more than ten years. In 1936 Bordet, the discoverer of the pertussis bacillus, reported favorably on a mixture of pertussis vaccine and diphtheria toxoid.[29] More recently reports on mixed immunization have appeared in this country.[30]

In 1941 a trial of combined immunization was begun in the Children's Clinic at Stanford. A mixture of aluminum hydroxide adsorbed diphtheria and tetanus toxoids containing twenty billion H. pertussis per cubic centimeter was used.[31] Only two injections of 1 cc. each were given. An interval of three months was used. Table 1 details the results of the serologic observations. The determinations here recorded apply only to children who should have but did not have any reinjections of any kind. Hence the antitoxin and antibody levels indicate the serologic immunity following the basic course of only two injections plus the slight added stimulus of a Schick test six months after the basic course.

It is apparent from the table that a satisfactory immune response was obtained with respect to diphtheria. Although the numbers are small the persisting uniform Schick negativity is gratifying. The tetanus antitoxin produced is rather remarkable. To my knowledge uniform levels of 0.1 unit or more after two and a half years have not been previously described. (This study will be reported in more detail elsewhere.) On the other hand, the pertussis agglutination titers are not satisfactory. In my experience children carrying

[31] Supplied by Cutter Laboratories

agglutinin in high titer (1:320 or more) are protected.[32] With lower titers they may or may not be. The levels here found are inferior to those observed in the past following 80 billion H. pertussis in isotonic solution of sodium chloride. Furthermore, 2 children in this group were reported to have had whooping cough.

In the light of the above observations the clinic immunization schedule has been modified by the insertion of a dose of pertussis vaccine midway between the two triple antigen injections.

Some such schedule of combined immunization is of particular value in public health quarters and in crowded dispensaries. In private practice the use of mixtures may often be found a convenience. Their principal disadvantage is not the slightly more pronounced local reactions but the difficulty involved in obtaining the optimal interval for each ingredient in the mixture. In private practice optimal time relationships need not be compromised when the child is being examined monthly. A conservative schedule for office immunization procedures is submitted in table 2. This schedule is based on my conclusions as to optimal time relationships for basic courses and reinjections.

CONCLUSIONS

For primary (basic) active immunization of infants the following preparations are recommended: against smallpox, calf lymph virus; against diphtheria and tetanus, alum precipitated toxoids or aluminum hydroxide adsorbed toxoids, and against pertussis, phase 1 H. pertussis vaccine in isotonic solution of sodium chloride or alum precipitated.

Frequent reinjections of tetanus toxoid are obligatory to maintain immunity. Reinjections of pertussis vaccine and diphtheria toxoid are important, as is also smallpox revaccination.

Combined immunization with mixtures of toxoids and H. pertussis vaccine is valuable in public health and dispensary practice. Combined immunization may often be a convenience in private practice.

ABSTRACTS OF DISCUSSION

Dr. Hulda E. Thelander, San Francisco: Although considerable attention is given to the immunizing agent little is given to the host or recipient of immunization, who probably is more variable than is the agent used. It is generally recognized that characteristics of the human race such as height, weight and intelligence quotient vary widely; when persons are arranged according to their measurements they will fall into typical variability curves. Immunity, or the capacity to be immunized, however, is an intangible characteristic which does not lend itself to easy measurement. Years ago, in the study of antitoxin levels after immunization it was considered that it would be desirable to demonstrate graphically that immunity, like other factors, showed variability. Difficulty arose, however, when the figures spread from 0.005 unit to 50 units per cubic centimeter of serum. Finally, by arranging the figures by multiples of ten, it was possible to plot a variability curve. The children were immunized by one of the standard methods, but the adults were given 0.1, 0.2 and 0.2 cc. at two week intervals, and severe reactors were continued at 0.1 cc. instead of increasing the immunization dosage to 0.2 cc. The curves for children and adults were similar. The object lessons derived from the study were two: first, that the relatively few persons who resist immunization are the ones to whom special attention must be given, such as larger doses, more injections and frequent boosters; second, that it is unnecessary to subject the majority of adults to the undesirable effects of large doses of toxoid, since most persons immunize as well with much smaller doses.

Dr. Alfred E. Fischer, New York: Every pediatrician must look forward to the time when his young patients will no longer scream with terror when they approach his office. The earlier age of injection and a decrease in the number of injections will go far to make the practice of pediatrics more tolerable. The morbidity rate for pertussis indicates the need for early immunization. Until recently it had been assumed, largely from animal experimentation, that the young infant was unable to produce antibodies effectively. Then Sako showed that if adequate amounts of phase I pertussis organisms were injected a good agglutination titer could be obtained in infants 4 to 8 weeks old. Moreover, his clinical results were satisfactory; fewer of the injected infants contracted pertussis on subsequent exposure than did controls. Furthermore, the immune response persisted. Recently Peterson, in as yet unpublished experiments, showed that infants less than 3 months of age produced adequate antibodies against pertussis and tetanus. On the other hand, the antitoxin level produced against diphtheria was not as high as that produced in older infants. Several groups of workers in New York are studying different combinations of antigens in various age groups. From the data at hand, one cannot as yet recommend a standardized procedure using triple antigens, that is pertussis, diphtheria and tetanus Needs might vary in different communities and even in the same community from year to year. Since there has been only 1 infant less than 6 months of age with diphtheria, and only 9 under 1 year of age at Willard Parker Hospital in the past seven years, there is no necessity for extremely early immunization against this disease in New York at present. Nor is tetanus immunization important in the young infant in this city; however, since it can be combined so readily with the diphtheria injection, one may as well administer the two toxoids together. Since active immunity tends to weaken after a time, the administration of a stimulating dose of antigen should become a well established procedure. The triple antigen in doses of 0.2 or 0.3 cc. would seem to be excellent for this purpose in a previously immunized infant, one year after basic immunization, as Dr. Miller has suggested, and perhaps every two years thereafter. A suggested immunization schedule is as follows: 4 months of age, smallpox vaccination (spring or fall); 5 months, first pertussis; 6 months, diphtheria—tetanus—pertussis; 7 months, diphtheria—tetanus—pertussis; 8 months, smallpox vaccination, if not done at 4 months; 9 months, diphtheria and tetanus; 14 months, Schick test; 2 years, diphtheria—tetanus—pertussis (stimulating injection); and two or three years later, a stimulating injection. Young infants tolerate smallpox vaccination well, so I can see no objection to vaccinating a healthy infant at 3 or 4 months of age except in extremely cold or hot weather. Early pertussis immunization is desirable, so the first of such injections can be started at 5 months of age.

Dr. John A. Toomey, Cleveland: I am chairman of that committee. Members of the committee are scattered over the United States, and there exist many different opinions about any procedure, however simple. Frequently, the committee has to stay put for a period of time before it can get even a semblance of agreement on a particular point. Consequently, the official opinion of the committee must of necessity lag a little behind the more decided advances suggested by Drs. Miller and Thelander. An opinion given by the committee must be on a point which is tried and universally accepted. That doesn't mean to say that the opinion is always right. For the past two years I have been on a national committee that has been studying the effect of multiple antigens. It first used five antigens. I won't go into this report because it is to be published later by the committee as a whole, but I will give the general substance of it. Five antigens were tried, including typhoid, scarlet fever and the three antigens reported on this morning. The reactions were severe, and even the persons on whom the antigens were tried, patients in an epileptic and mental institution, even those patients complained. Subsequently, it was found that the scarlet fever antigen was causing the trouble. The three antigens suggested by Drs. Miller and Thelander, tetanus, diphtheria and pertussis, have been tried by a national committee; after two years' work, their results will be reported by this committee at the American Public Health Conference in November, 1946. I agree with Dr. Thelander that there is no reason why adults should be immunized, especially against diphtheria, and also I agree with her that adults can be immunized with extremely small doses. There is some objection to the routine use of tetanus antigens. Two members of the committee of which I am chairman do not believe that it should even be used, but the majority feel that there is no objection to the use of the three antigens. I wondered if Dr. Miller could give some information as to whether he uses combinations in the subsequent booster dose. For instance, if he used the triple antigen and then subsequently has a child exposed to tetanus, will he give a booster injection of an antigen composed of two materials (diphtheria and tetanus) or will he use a single antigen, that is, a tetanus antigen? It has been said by some that when the mixed antigens have been used in the booster dose there have been a few reactions of an anaphylactic nature. I would like to ask him about that.

---

[32] Miller, J. J.; Silverberg, R. J.; Saito, T. M., and Humber, J. B.: An Agglutinative Reaction for H. Pertussis: Its Relation to Clinical Immunity, J. Pediat. 22: 644, 1943. Sako and others.[24]

DR. ERNEST WOLF, San Francisco: Whereas it is desired to prevent disease in childhood, one should at the same time be extremely careful that the relation between patient and physician also be saved. I make a great plea to all who make those schedules to minimize the number of injections necessary between the sixth and eighteenth month. At this age children are easily upset and are very much aware of what is done to them. Should it be proved that measures taken in the first four or five months give sufficient immunity to prevent later troubles, this would be the period of choice from the point of view of mental hygiene and patient-physician relations. When I see Dr. Miller's schedule of seven injections for infants between 7 and 15 months of age, I am a little afraid that pediatricians will have still more howling in their offices.

DR. JOHN MILLER JR., San Francisco: In answer to Dr. Toomey's question What agents are used for booster injections? circumstances dictate the choice. If a child is brought in with a wound, he is injected with 1.0 cc. of fluid tetanus toxoid regardless of the type of tetanus toxoid he received in the past. If a child has been exposed to whooping cough a booster injection of 20 billion H. pertussis organisms in isotonic solution of sodium chloride is given. As speed in raising antitoxin or antibody titer is desired, adsorbed preparations are not the agents of choice. On the other hand, for routine reinjections at 6 years of age a mixture of antigens is employed. H. pertussis vaccine mixed in the syringe with adsorbed tetanus toxoid is given. If the Schick test done at this visit becomes positive I then give the child diphtheria toxoid alone. As I mentioned previously, I am guided in my dosage by the child's reaction to the Schick control test of diluted toxoid. I do not give mixtures containing diphtheria toxoid to the child 6 years of age unless I know that the child is not sensitive to diphtheria toxoid.

Cardiac Lesions in Rheumatoid Arthritis.—We used to be taught, even until the last year or two, that rheumatoid arthritis was wholly different from and not in any way related to rheumatic fever. These postmortem studies show that this is not so; they reveal that, in a high percentage of cases of chronic arthritis, changes are found in the heart which are wholly indistinguishable from the changes in the heart in cases of rheumatic fever. It really is astounding when we think that postmortem examinations by reliable pathologists show that 30 to 60 per cent of patients dying with rheumatoid arthritis have cardiac lesions, valvular lesions of the heart that are identical in every way with the valvular lesions found in rheumatic fever. —Bohan, Peter T.: The Concomitant Diseases or Conditions Associated with Polyarthritis, *Postgraduate Medicine,* May 1947.

PULMONARY ARTERIOVENOUS ANEURYSM WITH SECONDARY POLYCYTHEMIA

Report of the First Case Treated by Lobectomy

W. H. BEIERWALTES, M.D.
and
F. X. BYRON, M.D.
Ann Arbor, Mich.

In 1938 the attention of the members of the medical profession was first called by Rodes [1] to congenital pulmonary arteriovenous aneurysm with secondary polycythemia as a cause of cyanosis. Since this first report only 7 of these cases have been reported,[2] although 2 others without polycythemia have been noted,[3] and rupture of the arteriovenous fistulas has been recorded as a cause of death in infants.[4] In none of the 7 cases just mentioned [2] was the condition diagnosed correctly by the first physician to see the adult patient. As 3 of these patients were completely cured by total pneumonectomy [5] and as the lesion has been recognized more frequently in the last eight years, it is important that physicians become aware of this condition as a cause of cyanosis.

Since our patient is the first to be treated by lobectomy and since this curable condition is so seldom diagnosed, we wish to report our case and review the diagnostic features of this lesion.

REPORT OF CASE

History and Preoperative Data.—M. M., a white unmarried woman aged 27, was first seen in the medical outpatient clinic of the University Hospital, Ann Arbor, Mich., on Oct. 26, 1945 with the chief complaint of "blueness." Mild cyanosis had been noted since birth but had increased in intensity in the last two years. She stated that it had occasionally decreased to almost complete disappearance for intervals as long as two weeks. From birth till the age of 9 years she had had moderate epistaxes once a week. After the age of 9 years these episodes decreased in frequency. She had also been bothered since her earliest memory by the prompt appearance of paresthesias in the extremities on the left side when she would lie on this side. Three or four years before admission she had noted the onset of episodes of syncope (lasting about three minutes), dizziness and paroxysmal nocturnal dyspnea occurring about once a month.

In September 1945 she consulted her physician, Dr. Cecil Corley of Jackson, Mich., because of pain in the legs extending from the feet to the hips and present since birth. Dr. Corley noted the cyanosis and obtained roentgenograms of the chest which showed no evidence of congenital heart disease but did show a tumor in the right lower lung field. He then referred her to the University Hospital, Ann Arbor, Mich., for diagnosis and treatment.

From the Departments of Internal Medicine and Surgery, University of Michigan.

The intake of drugs by the patient in the past had been limited to one or two tablets of acetanilid as often as once a month. Of significance in the family history was the fact that the patient's mother and living brother had had frequent epistaxes all their lives. The mother was described as having been exactly comparable to the patient in her degree of physical underdevelopment and cyanosis. She died at the age of 37 of "pneumonia at childbirth." When the brother was 12 years of age he was told by his physician that he had an incurable "rheumatic heart." He is apparently well now at the age of 30 and is not cyanotic

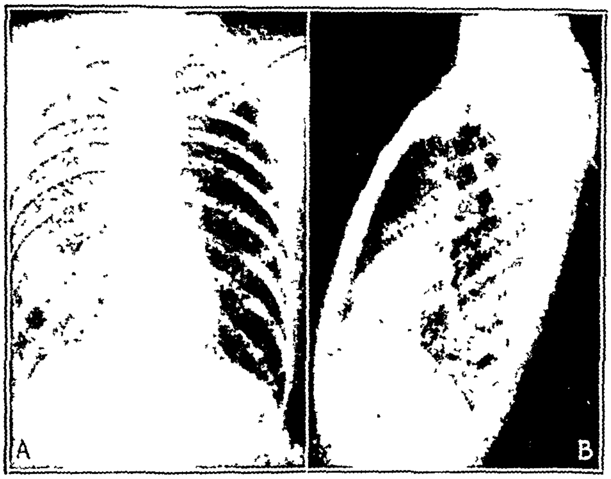

Fig. 1.—*A*, preoperative roentgenogram showing the arteriovenous aneurysm in the right lower lung field. *B*, right lateral view

On physical examination the patient was found to be 5 feet 2 inches (158 cm.) tall and to weigh 89 pounds (40.4 Kg.). She was poorly nourished and poorly developed, with masculine distribution of body hair and hypoplastic breasts. Her blood pressure was 110 systolic and 80 diastolic in the right arm, in the reclining position, while the blood pressure in the left arm could not be obtained. The radial pulses were strong and equal bilaterally. The patient exhibited generalized cyanosis, most pronounced over the face, lips and hands In addition close inspection revealed numerous pinhead-sized to pinpoint-sized blue spots, which appeared to be small, superficial hemangiomas, on the face, lips and palms. The lung fields and heart were entirely normal to physical examination. The spleen was not enlarged. The extremities showed only minimal clubbing of the fingers. The superficial veins were unusually prominent. The rest of the physical examination was entirely noncontributory.

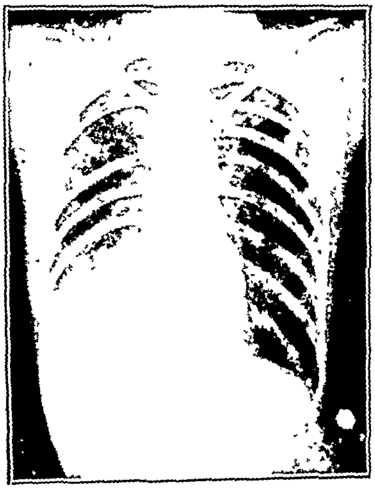

Fig. 2.—Postoperative roentgenogram of the chest, with aneurysmal communication removed with lower lobe of the right lung.

Laboratory examinations included a complete blood count with a hemoglobin level of 21.6 Gm. (138 per cent). The red blood cell count was 8.2 million per cubic millimeter with a hematocrit reading of 75 volumes per cent. The mean corpuscular volume was 91 cubic microns. The white blood count was 7,000 per cubic millimeter with a normal differential. The sedimentation rate was 1 mm. per hour by the Wintrobe method. Urinalysis and the Kahn test on the blood were negative. These findings together with the roentgenograms sent by Dr. Corley suggested the diagnosis of pulmonary arteriovenous aneurysm with secondary polycythemia.

The patient was advised to have a lobectomy as treatment for her disease. She returned on March 18, 1946, at which time the history, physical examination and laboratory studies were not significantly changed. Roentgenologic studies showed a 3 cm. area of increased density in the medial portion of the right lower lung field, half way between the anterior and posterior surfaces of the lung. Pulsations were definite but very small. A tail-like projection seemed to extend from this area of increased density to the hilar vessels on that side (fig. 1). An electrocardiogram, read by Dr. F. N. Wilson, was well within normal limits. Oxygen saturation studies done by Dr. Vivian Iob showed the arterial blood saturation, based on hemoglobin content, to be 77 per cent and the venous oxygen saturation to be 61 per cent. The arm to tongue (dehydrocholic acid) circulation time was 12 seconds, the normal being 10 to 16 seconds. The vital capacity was 3,000 cc.

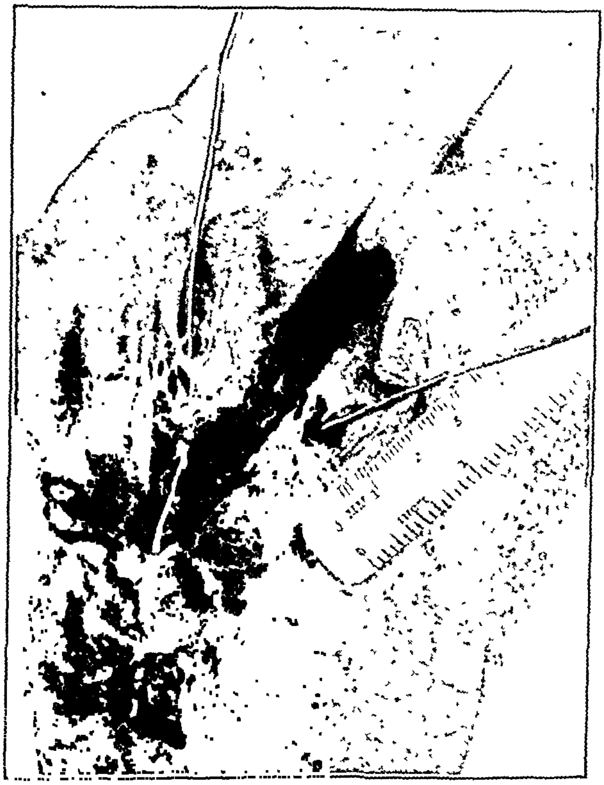

Fig. 3—The aneurysm, sectioned, with arterial side on the right and venous side to the left. The photograph was supplied by Dr C. V. Weller, chairman of the Department of Pathology.

Operative Observations.—On March 21, 1946 a lobectomy of the lower lobe of the right lung, was performed by one of us (F. X. B.) under intratracheal ether vapor and oxygen anesthesia. With the patient in the left lateral decubitus position the incision was made along the course of the fifth rib. The rib was resected subperiosteally. Although lobectomy was contemplated (we were under the impression that the aneurysm lay in the posterior aspect of the middle lobe) the fifth rib was resected rather than the seventh because we were aware of the experience of Jones and Thompson[2d] who had planned a lobectomy of the upper lobe for their patient but were forced to perform a pneumonectomy because of a vascular abnormality (absence of the inferior pulmonary vein). On opening the pleura no abnormalities were observed, and on separating the fissure between the middle and lower lobes the aneurysm was immediately apparent on the anterior surface of the lower lobe of the lung, with its upper margin approximately 6 cm. from the hilum of the lobe. The aneurysm itself measured about 4 cm. in diameter, was dark red and so thin-walled that the blood could be seen passing through it. There was no visible pulsation, and no thrill was palpable.

The entire fissure surface of the lower lobe, superior to the aneurysm, was covered with a fine meshwork of telangiectatic vessels, which made dissection of the hilum somewhat more hemorrhagic than is usual. After it had been ascertained that both an inferior and superior pulmonary vein were present, the lower lobe of the right lung was resected by the individual dissection and ligation technic. The fissure between the upper lobe and the apex of the lower lobe was incomplete, division being accomplished between hemostats with oversewing of the cut surface of the upper lobe. Postoperatively the chest was drained by means of an intercostal catheter for forty-eight hours.

The arterial and venous paths to the aneurysm could be demonstrated in the resected lobe (fig. 3)

Postoperative Course.—The postoperative course was uneventful, one thoracentesis being necessary after removal of the drainage tube.

Immediately after the operation there was a noticeable decrease in cyanosis even though polycythemia was still present. During the subsequent hospital days progressive diminution of the cyanosis occurred. The hemoglobin content was 17.5 Gm. on the fourth postoperative day. On the eleventh postoperative day studies of the venous and arterial blood were carried out. Data on the arterial blood were as follows: hematocrit reading 57.7 volumes per cent, hemoglobin 17.9 Gm., oxygen content 21.8 volumes per cent, oxygen saturation 23.7 volumes per cent and the per cent of oxygen saturation had risen to 92.2 per cent (as compared with the preoperative value of 77 per cent). The percentage of venous oxygen saturation was 60. The patient was discharged on April 3, 1946, the thirteenth postoperative day.

On May 1, 1946 she returned for a follow-up examination. She stated that she no longer had leg pain and felt well except for some residual thoracic discomfort. Examination revealed the physical signs incident to lobectomy, mild cyanosis and generalized desquamation of the skin. The blood pressure was now obtainable in the left arm and was 110 systolic and 78 diastolic. Her hemoglobin level on this visit was 18.4 Gm. (118 per cent), as compared with the preoperative level of 21.6 Gm. (138 per cent). Similarly the hematocrit reading was 62.5 volumes per cent and the red blood cells count was 6.7 million, as compared with the preoperative levels of 75 volumes per cent and 8.2 million.

In June roentgenograms of the chest showed a satisfactory operative result and did not disclose other aneurysms (fig. 2).

COMMENT

The clinical picture in this case closely resembles that of the 7 previously reported cases of pulmonary arteriovenous aneurysm with secondary polycythemia. Seven of the 8 patients, including ours, have been aged 20 to 27 years, the other 1 being 40 years old.[2e] Five have been men and three women. The chief complaint on admission has varied so widely as to be of little aid in making the final diagnosis. The symptoms, however, have been remarkably constant and consist of (1) cyanosis, (2) clubbing of the digits and (3) symptoms of anoxia.

1. *Cyanosis.*—Half of the patients had exhibited some degree of cyanosis since birth. The others showed cyanosis for two to sixteen years.[6] It is notable that cyanosis secondary to a pulmonary arteriovenous aneurysm can occur in the absence of polycythemia.[3]

2. *Clubbing of the Digits.*—Clubbing of at least the fingers was present in all cases. The degree of clubbing roughly paralleled the size and number of the pulmonary fistulas. Our patient had but minimal clubbing secondary to one 3 by 2 cm. fistula.

3. *Symptoms of Anoxia.*—The most commonly observed symptom of anoxia was dyspnea, which was present in 6 of the 8 cases.[7] Only cyanosis was noted by Jones and Thompson.[2d] Other common symptoms of anoxia manifested by the majority of patients were mild or decided syncope with or without convulsions, paroxysmal nocturnal dyspnea, substernal oppression and paresthesias. These symptoms of anoxia are probably secondary to the extremely low oxygen saturation of arterial blood observed in patients with this condition.

A peculiar and unexplained aspect of symptomatology in 3 of the cases is unilateral complaints related to the left side of the body. One patient [2a] could not lie on the left side because it caused him to cough. This symptom was relieved by removal of the fistula in the left lung by left pneumonectomy. Our patient could never lie on her left side because the extremities on the left would immediately develop intense paresthesias. This complaint disappeared when the fistula on the right was removed by lobectomy of the lower lobe of the right lung. In another patient [3a] there developed numbness in the left arm and shoulder and weakness of the left hand shortly before admission to the hospital. Unfortunately we do not know the effect of treatment in this case, since the patient died during angiography.

The family history of heredity of this lesion is interesting. In 4 instances this point was omitted [8] and in 2 the presence of cyanosis in other members of the family was denied.[9] In the case of Adams and his associates [2a] the father of the patient had had blue spots on his lips and nose bleeds similar to those of the patient. This was also true of other men in the family. The father had had a roentgenogram of the chest which had shown "shadows." The description of our patient's mother suggests a hereditary tendency. The brother's history is suggestive and is being investigated at the present time.

The only constant observations on physical examination in the reported cases were cyanosis and clubbing of the fingers. Strangely enough, only 3 patients had a murmur produced by the vascular communication.[10] In the majority of the reports no pulsation of the communication was noted by roentgenologic examination. No cardiac abnormality or abnormality of the pulse pressure or of the pulse rate was present. Five of the 8 patients were underdeveloped, presumably due to the prolonged anoxia caused by the congenital lesion.[11] Five of the 8 patients had cutaneous hemangiomas.[12] These were located on the face, on the lips, behind the ear and on the palms. Since they easily pass unnoticed, it is entirely possible that all patients with this type of lesion have had them. The surface of the lung at surgical intervention or autopsy is also frequently covered with these small hemangiomas. Since the spleen is never enlarged, with the possible exception of the case of Goldman [2c] in which it was "just palpable," and since the white blood count is never elevated, the possibility of polycythemia vera may be eliminated. In spite of this fact the disease of 2 patients [13] with pulmonary aneurysms was so diagnosed and treated.

Most striking of laboratory observations is the secondary polycythemia with red blood cell counts ranging from 6.5 million [2e] to 11.45 million.[2c] The hemoglobin level in these cases ranged from 118 per cent to 138 per cent. The highest hematocrit reading recorded [2b] was 80 volumes per cent. The oxygen saturation of the arterial blood ranges from 70 to 80 per cent. The vital capacity and the blood circulation times are always within the normal range, although the latter approaches the lower limit of normal.

In none of the 8 cases was the diagnosis made by the first physician to see the patient. In 3 cases more fistulas were found at pathologic examination than by roentgenologic examination.[14] Yet surgical extirpation of the main fistulous communication [2a] has abolished the symptom complex. Apparently the most frequent mode of death is by pulmonary hemorrhage [15] as in pulmonary arterial aneurysms. The fact that patients treated have been reported to be cured at five and a half months,[2a] one year [2b] and seven months [2d] after pneumonectomy suggests that surgical treatment is worth while. Pneumothorax on the side of the lesion is worthless either as a diagnostic or therapeutic procedure, since no change in the clinical picture occurs even though the lung is thoroughly collapsed.[2b]

SUMMARY

Cyanosis secondary to congenital pulmonary arteriovenous aneurysm with secondary polycythemia is one type of congenital cyanosis that can be completely cured by surgical intervention. Although this lesion is supposedly extremely rare, the fact that all 8 cases have been diagnosed since 1938 suggests that many of these lesions have been missed in the past.

The most important prerequisite for making the diagnosis is an awareness of this lesion as a cause of cyanosis and polycythemia. The clinical picture consists of a patient of either sex, usually from 20 to 30 years of age, with cyanosis recently increased in intensity. Symptoms of anoxia predominate with hemorrhage from superficial hemangiomas, usually from the nose. Cyanosis has often been present in siblings or parents. Physical examination reveals clubbing of the digits and cyanosis. Maldevelopment and superficial hemangiomas are also present, but there is usually no abnormality of the heart, pulse pressure or pulse rate and no pulmonary vascular murmur.

The vital capacity and blood circulation times are normal, but secondary polycythemia is present. The diagnosis is clinched by the roentgenologic observation of tumor-like shadows in the lung. These shadows usually do not pulsate but do usually show communications with the hilar vessels. The patient is completely cured by pneumonectomy, lobectomy or local excision of the fistula.

THE MECHANISM AND MANAGEMENT OF INJURIES OF THE HEAD

E. S. GURDJIAN, M.D.
and
J. E. WEBSTER, M.D.
Detroit

Great strides have been made in the study of the mechanism and management of injuries of the head during the past ten years. In the present paper it is proposed that the more important of these studies be analyzed.

MECHANISM OF CRANIOCEREBRAL TRAUMA

Injury to the head may occur by direct or indirect violence. In a direct blow the head is relatively fixed and the striking object is in motion. A direct blow may cause compression of the intracranial contents by deformation of the skull, and it may set the head to motion (acceleration). In indirect blows the head in motion comes in contact with a nonmoving or slower moving object. Under these circumstances, compression and deceleration may obtain. Compression, deceleration and acceleration frequently coexist in the usual injuries such as auto accidents, falls, etc.[1] With direct blows the lesion is more likely to be limited to the head, whereas with indirect violence the injuries are usually multiple.

Deformation of the skull and acceleration of the head result in increased intracranial pressure waves, with steep gradients. The presence of the craniospinal junction at the foramen magnum may be an all-important factor in the involvement of centers in the brain stem. Such an opening may cause pressure gradients between the cranial cavity and the spinal canal, with encroachment on medullary structures.

The effects of craniocerebral trauma in the experimental animal are manifested by alterations of function of centers in the brain stem, namely the vasomotor, the respiratory and the sensory-motor centers supplying the face. The generalized body rigidity frequently seen results from stimulation of the pyramidal tracts in the brain stem.[2] Besides these disturbances in the brain stem, hemispheric abnormalities have been demonstrated by the electroencephalograph, which has shown increase in amplitude and frequency of pattern immediately following impact in some experiments.[3] In others, there has been an initial depression of the electroencephalographic pattern.[4] It is proved beyond doubt that death from acute injury of the head in the experimental animal results from direct damage to medullary centers. Autopsies in human beings found dead at the scene of accident reveal pathologic changes in the form of petechial hemorrhages in the brain stem similar to those observed in the experimental laboratory.

From the Department of Surgery, Wayne University College of Medicine and Receiving Hospital, and the Department of Neurosurgery, Grace Hospital.

Read before the Section on Surgery, General and Abdominal, at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 3, 1946.

It is reasonable to assume that in the human being death soon after injury is due to medullary paralysis, as it has been found to be in the experimental animal.

The effects of trauma of the head can be correlated with the amount of absorbed energy whether the head is fixed or free to move. In the experimental animal (dog), 200 inch-pounds of energy absorbed by the head in 1/1,000 to 3/1,000 of a second or less, causes profound pathophysiologic effects, usually terminating fatally. When the head is free to move, the possibility of mass movements of the brain is greater.

The definition of the term "concussion," or immediate post-traumatic unconsciousness "unassociated with microscopic or macroscopic lesions of the brain," should be changed in the light of recent experimental work.[5] New pathologic technics have revealed the presence of intracellular changes even in the most minimal degrees of concussion. The damage to the cells may or may not be reversible.

We have had the opportunity to study deformations of the skull and changes in intracranial pressure at the time of impact by certain new electronic and engineering technics. For the study of deformations of the skull, we have used (1) the strain gage–cathode ray oscilloscope method and (2) the "stresscoat" technic. The former is a sensitive, quantitative method of determination of deformation; the latter permits the study of the direction and the path of strains following a blow.

Strain Gage–Cathode Ray Oscilloscope Method.—The strain gage is a length of wire 1/1,000 inch (0.0254 mm.) in diameter which is cemented to the surface of the skull with methyl methacrylate cement.[6] Deformations of the skull following a blow also deform the strain gage. Inbending of the skull causes a shortening of the wire, whereas outbending results in a lengthening of the wire in the strain gage. Shortening of the wire results in decrease in the resistance, and lengthening, an increase in the resistance through the gage. Such changes in resistance, due to deformations of the skull, are shown on the oscillograph, and permanent records are obtained by photography.

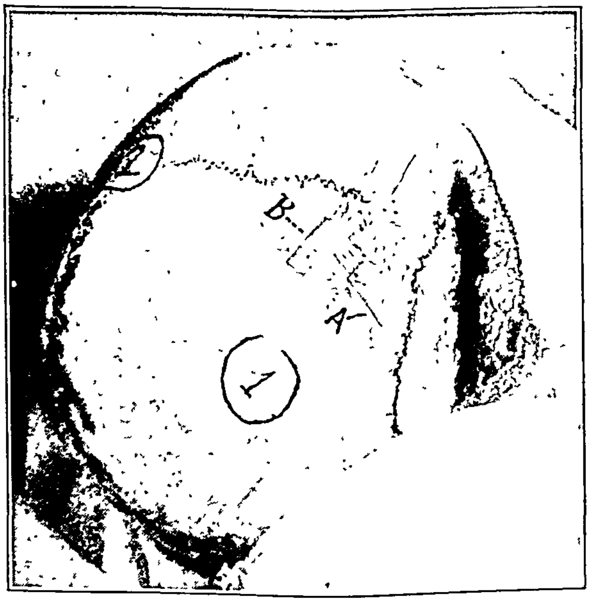

Fig. 1.—A human skull prepared for strain gage studies of deformation from hammer blows; 1 and 2 are the areas of impact, and A and B are the strain gages cemented to the surface of the skull. The records obtained from such preparations are seen in figure 2. Previous experimental work has shown that the strain gage measurements of the dead skull with contents intact are similar to those obtained on the skull of the animal under anesthesia. It is felt, therefore, that these studies on the human skull may represent premortem conditions.

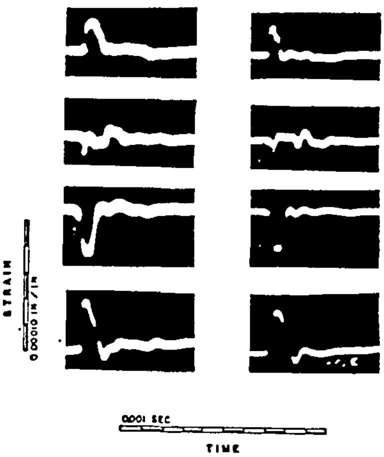

Fig. 2.—To the left are records of one human autopsy specimen and to the right are records of another specimen. The blows were administered as indicated in figure 1. Upper row, hammer blow at point 1 with recording at strain gage A; second row, blow at point 2 and recording at strain gage A; third row, blow at point 1 and recording at strain gage B; fourth row, blow at point 2 with recording at strain gage B. Upswing denotes tension, and downswing denotes compression. Total time of disturbance was 1/250 of a second. Initial deformation time was 1/2,000 to 1/5,000 of a second. There were three to six oscillations during the disturbance at the rate of 900 to 1,200 cycles per second.

The measurements with the strain gage of deformations in the skull of the dog under pentobarbital sodium anesthesia were similar to those obtained twenty-four hours after the death of the animal with intracranial contents intact. The dry skull is not suitable for this study, owing in part to the absence of the dampening effect of the intracranial contents. Since strain gage measurements of deformations of the skull were known to be the same in the living under pentobarbital sodium anesthesia and in the dead dog with intracranial contents intact, human autopsy material, soon after death, was studied with this technic. It was concluded that the findings in the autopsy specimens represent conditions present in the living (fig. 1).

On the delivery of a blow to the human skull, the time of the initial deformation varied from 1/5,000 of a second to 1/2,000 of a second. The total elapsed time for the deformation pattern was between 1/200 to 1/250 of a second. In different parts of the skull there were 3 to 6 cycles during the deformation process. These occurred at the frequency of about 900 to 1,200 cycles per second (fig. 2).

The pattern of deformation shown by this method is the same irrespective of the energy of the blow. Whether the impact is the result of injury by hammer, brick or fall, the deformation pattern is also the same provided that there is no perforation of the skull from high velocity blows.

"Stresscoat" Studies of Deformations of the Skull.—By the "stresscoat" technic, which employs a strain-sensitive lacquer, the direction and the path of strains were studied. With a lacquer of a given sensitivity applied to the surface of the skull, deformations of the order of 0.0005 to 0.0015 inch per inch resulted in cracks in the lacquer coating. These cracks demonstrate the paths of the strains following the blow.[7] Experimental observations have shown that the deformation patterns in the living animal under anesthesia, in the dead animal with intracranial contents intact and in the dry skull of the same animal are similar.

[7] Gurdjian, E. S., and Lissner, H. R.: Surg., Gynec. & Obst. **81**: 679, 1945.

The magnitude of strain may be different, but the paths and directions are the same.

By a study of freshly obtained skulls, it was found that blows in various regions of the skull caused discrete areas of deformation in the region of impact as well as in remote parts. In the occipital region, cracks appeared in the lacquer with half the amount of absorbed energy as compared with the frontal region. This technic measures only tensile (tearing apart) strains; compression (pushing together) strains are not seen. Up to the present time we have studied the behavior of the external surface of the skull and have no information concerning what may happen on the interior. Tensile deformations on the internal surface of the skull are undoubtedly important and may result in fracture lines. From a study of our present material it appears likely that a certain number of fractures, due to general deformation of the skull, may occur from tension, or an outbending, following the initial inbending, after impact (figs. 3 and 4).

On the basis of our work with the "stresscoat" technic thus far, the following conclusions may be drawn:

1. Threshold deformations in different regions of the skull are obtained with varying energies. For instance, it takes twice as much energy to cause cracks in the frontal as it does in the occipital region.
2. Some fractures may occur from outbending following the initial inbending of the skull.
3. Many fractures occur parallel to lines of stress shown in these studies.
4. From the position and the direction of the skull fracture, one may be able to guess the area of impact which caused the fracture.
5. "Contrecoup" cracks in the lacquer were obtained with occipital blows in 1 specimen. The cracks following an occipital blow in this specimen appeared at the frontozygomaticosphenoid junction on one or both sides

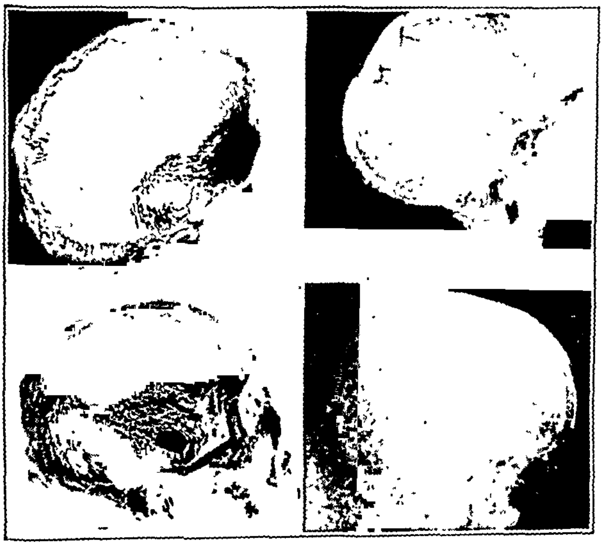

Fig. 3.—To the left, "stresscoat" preparation *in a dry skull following* a posterior parietal blow. Note that the direction of the cracks in the lacquer are downward and forward toward the temple. To the right are two roentgenograms with fracture lines extending downward and forward toward the temple from the posterior parietal region. The upper roentgenogram also shows a depression *of the posterior* parietal region at the midline. It is reasonable to assume that the point of impact was in this region, with resultant depression *and also fracture* lines extending downward and forward toward the temple on both sides, paralleling the stresscoat lines of crack. In the lower roentgenogram the fracture is more widely separated in the parieto-occipital region near the midline. This is the region of the greatest stress from the blow, with the fracture extending downward and forward, eventually becoming a *thin line, to disappear* in the temple.

Intracranial Changes in Pressure at the Time of Impact.—Increase in intracranial pressure occurs as a result of the deformation of the skull and acceleration or deceleration of the head. In the ordinary case of head injury the increase in intracranial pressure is wavelike or directional and may not necessarily involve the entire cranial cavity because of the rapidity of the changes. Steep pressure gradients, lasting in the neighborhood of $^{1}/_{1,500}$ of a second or less, may result in shear and tear of tissues in the path of the pressure wave. In a bullet wound of the cranial cavity the expended energy is so intense that the entire cranial cavity may undergo an explosive effect, due to a tremendous increase in intracranial pressure.

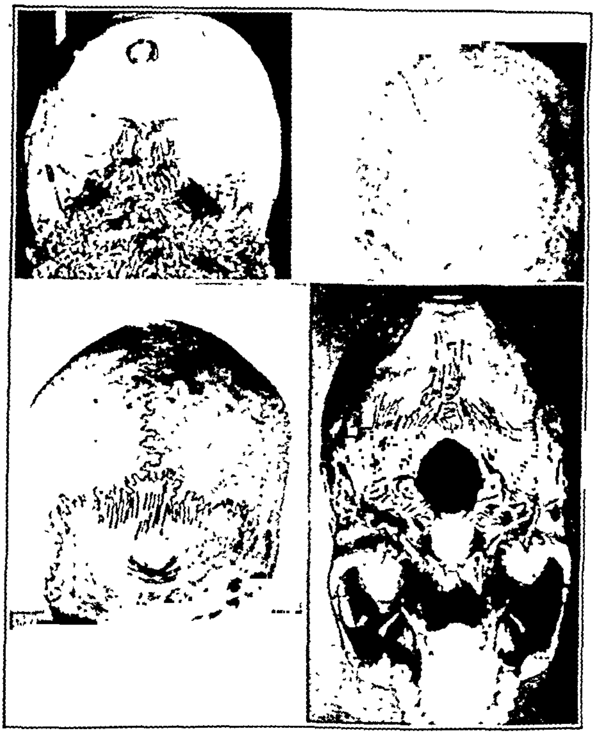

Fig. 4.—"Stresscoat" preparation in a cadaver skull and two views of a dry skull following a midoccipital blow. Note the direction of the cracks in the lacquer toward the foramen magnum. In the upper right quadrant is a roentgenogram showing an occipital fracture extending down to one side of the foramen magnum paralleling the lacquer cracks in the stresscoat preparations.

A study was made of intracranial pressure by the use of a pressure plug–cathode ray oscilloscope method. The electrical conductivity in an electrolyte varies with the pressure exerted on the solution.[8] By using this principle, it has been shown that a blow on the skull causes an increase in intracranial pressure at the site of the blow, with the pressure in the negative phase at a point diametrically opposite the area of impact. Working with the experimental animal (dog) it was found that the maximal increase in pressure was obtained in $^{1}/_{1,500}$ of a second following impact.[6] The period of change in intracranial pressure was in the neighborhood of $\frac{1}{200}$ to $\frac{1}{250}$ of a second. Three to five oscillations occurred during the period of disturbance.

J., and Koehler, W. A.: Principles and Applications of Electro-Chemistry, ed. 3, New York, John Wiley & Sons, Inc., 1935, vol. 1, p. 305.

As a result of the deformation of the skull, the increase in intracranial pressure and the mass movements of the brain, certain primary pathologic conditions ensue. These include cell damage, fracture, contusions and lacerations of brain tissue and intracranial hemorrhage.

CHEMICAL STUDIES IN EXPERIMENTAL HEAD INJURY

The arteriovenous differences in oxygen, carbon dioxide and glucose (samples of blood from the femoral artery and the sagittal sinus) remain within normal limits in moderately and severely injured experimental animals. In the normal brain, chemical studies on specimens frozen with liquid oxygen revealed the presence of 10 to 20 mg. of lactic acid per hundred grams of cerebral tissue.[9] The study of lactic acid in the brain of animals subjected to inhalation of low oxygen revealed an increase in the lactic acid proportional to the degree of the anoxia. It has also been shown that the lactic acid in the postmortem brain tissue is markedly increased. The study of the amount of lactic acid in the brain is thus a measure of the normalcy of the oxidative processes in that tissue. The brain of the experimental animal subjected to cranial injury revealed normal values except in the areas of contusions and lacerations. At such sites the lactic acid was markedly increased, denoting evidence of the defective local oxidation of glucose.[10]

Specimens of brain tissue by this technic were obtained as early as fifteen seconds after impact, and it was found that the "concussive" phenomenon is accompanied by normal levels of lactic acid. The concept that anemia of the brain at the time of impact is the cause of the post-traumatic unconsciousness is well disproved.[11]

In the experimental animal the use of a high concentration of oxygen, and oxygen with 5 per cent carbon dioxide, for as long as forty-eight hours does not materially change the disturbed oxidative mechanisms in traumatic contusions. However, it was found that when the animal was maintained at anoxic levels of oxygen, the addition of carbon dioxide increased the percentage of oxygen saturation (unpublished data).

COMPOUND FRACTURES, GUNSHOT AND OTHER PENETRATING WOUNDS

The management of penetrating wounds and the mechanism of wounding by high velocity missiles have received considerable attention during World War II.[12] The "temporary" cavity about the passing bullet, so beautifully shown by Butler, Puckett, Harvey and McMillan[13] and Black, Burns and Zuckerman,[14] is the cause of the extensive pulping of brain tissue at considerable distances from the region of the track. With this picture clearly in mind, it is no wonder that the successful management of such cases depends on the thorough debridement of the pulped brain, removal of foreign particles and fragments of bone. The long tedious technic of osteoplastic flap has been replaced by a complete removal of the area of shattered bone with a rongeur. If at all possible, the dura is closed if necessary with the use of fascia lata, pericranium, or temporal fascia. In extensive loss of tissue, all effort is made to cover the exposed brain with transposed scalp. Exposures are made through long curved incisions in order to enable the complete excision of the wound of entrance. The management of the cases in which there is infection, particularly those with abscesses of the brain, has been simplified by the use of chemotherapy and penicillin and by a policy of a complete excision of the infected brain, foreign bodies and fragments of bone[12] (fig. 5).

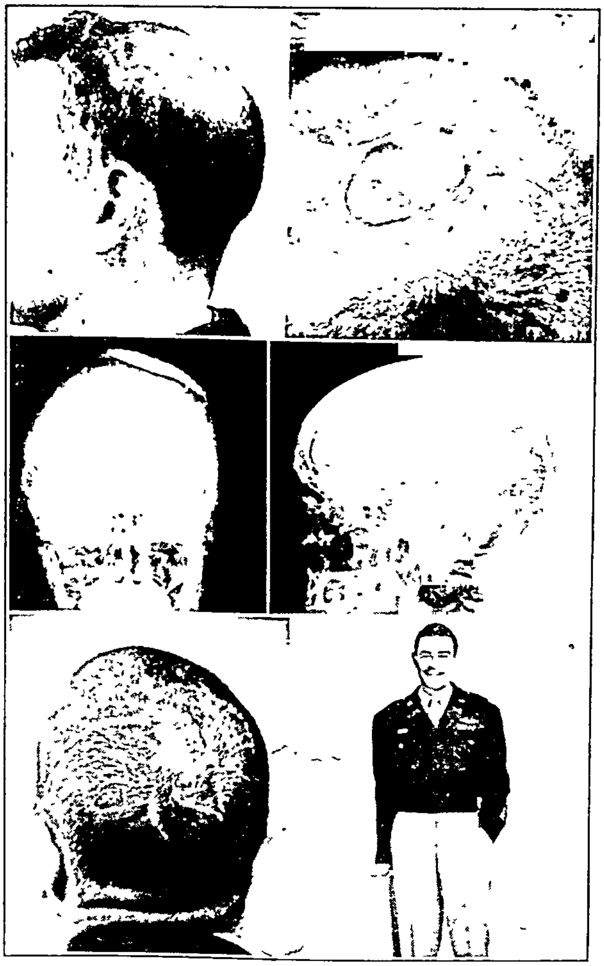

Fig. 5.—In the upper row are shown the posteroanterior and lateral views of an abscess of the brain due to penetrating wound by shell fragment treated by exteriorization, excision of abscess, shell fragments and necrotic brain tissue, followed by closure with fascia lata. Ten days later the fascia lata transplant was removed and a split thickness graft of skin was used. The middle row, following tantalum repair of skull defect. Lower row, the patient as he appears today.

In cases of civilian gunshot wounds of the brain, if the patient shows evidence of resuscitation by transfusions and other therapy, a complete and thorough debridement of his wound should be undertaken as soon as possible. But if, because of his poor condition, he is not operated on for two or more days, a delayed primary debridement may be safely accomplished. In a case of a gunshot wound of the right frontotemporal region, the debridement was done four days after

admission to the hospital. Almost all of the frontal lobe on the right side was removed, the dura was repaired with temporal fascia and the wound was closed in layers without draining. No complications arose and the wound healed by primary intention.

In the management of compound and simple depressed fractures in civilian life, some preoperative forethought in planning may minimize postoperative defects (fig. 6). In the absence of a torn dura, some of the fragments of bone may be used to advantage to obviate a later repair of the skull defect. The use of an inanimate transplant at the time of repair of a depressed fracture, as advocated by Gardner[15] may be undertaken with confidence except in cranio-orbital and frontal sinus wounds, where later repair of the defect is preferable, since the purpose of the primary operation is to obviate intracranial infection by preventing the formation of cranionasal fistulas.

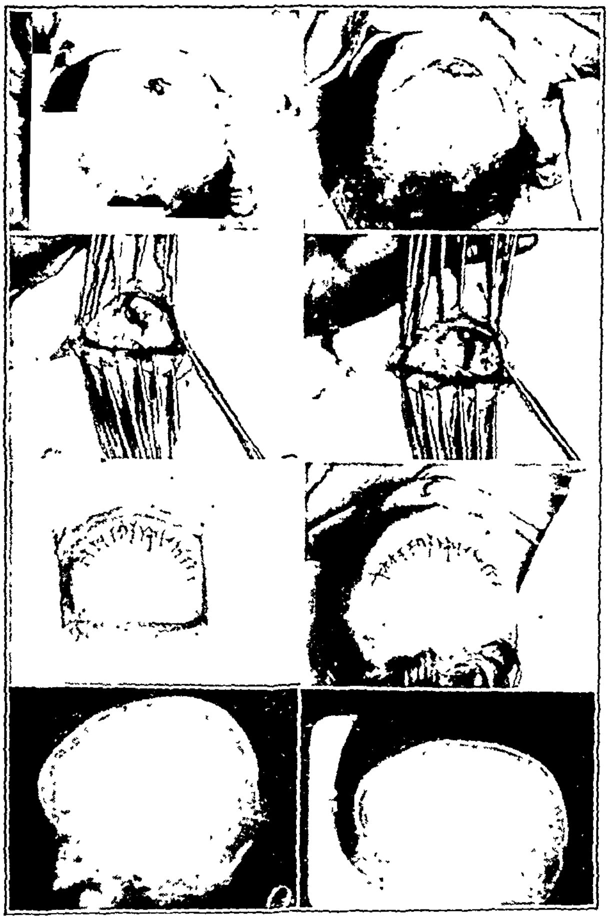

Fig. 6.—Compound depressed skull fracture of the midfrontal region at the hairline. The laceration was excised through a curved excision. The dura was found intact. The depression was elevated with little loss of bone tissue. Some preoperative forethought will obviate postoperative defects which might necessitate later repair.

In compound fractures, the initial wound may be excised in toto in the greatest majority of the cases by the use of long curved incisions (fig. 6). This is preferable to the usual method of excising only the edges of the wound.

The repair of skull defects has received considerable attention during World War II. Osteoperiosteal transplant from the outer table of the skull may be used for small defects and for the younger patient. Tantalum[16] and methyl methacrylate[17] have been proved to be sufficiently inert to make their use safe in the larger defects of the skull. The preparation of the transplant before operation for a satisfactory postoperative result is important, and has been suggested by several authors.[18]

CONCLUSIONS

1. Head injury may be by direct or indirect violence. Compression, acceleration or deceleration ensue. In most injuries a combination of compression, acceleration and deceleration takes place.

2. The amount of absorbed energy by the head in an optimum period of time governs the severity of the physiologic effects, whether the head is fixed or free to move.

3. A blow may result in deformation of the skull, increase in intracranial pressure and mass movements of the brain. The latter is more frequent when the head is free to move.

4. Fracture from general deformation of the skull may result from an outbending following the initial inbending after impact. Depending on the shape and velocity of the injuring object, there may be a localized or a generalized deformation.

5. Most fractures, including depressed fractures, result from tension (tearing apart) rather than from compression.

6. The oxidative processes of the brain proceed in normal fashion after moderate and severe head injuries, except in areas of contusion and laceration of the brain. At such sites there is a defective oxidation of glucose. In the experimental animal the arteriovenous differences of oxygen, carbon dioxide and glucose are within the range of normal in the moderately and profoundly injured.

7. In civilian life many simple and compound depressions may be repaired in such a manner as to prevent defects of the skull.

8. When it is necessary to repair a skull defect, an osteoperiosteal transplant from the outer table of the skull may be used for small defects and in the young. Tantalum and methyl methacrylate may be used for the larger defects. In some cases the repair of the defect may be undertaken at the time of the primary operation.

9. In gunshot wounds of the brain, operative treatment is indicated as soon as the patient's condition permits. With the use of chemotherapeutic agents, penicillin and early debridement, intracranial infection develops in few cases.

ABSTRACT OF DISCUSSION

Major Earl Walker, Cushing General Hospital: One has noted both in civilian and military experience that patients who suffer minor wounds to the head will frequently lose consciousness, whereas other patients suffering severe compound wounds of the skull will have no period of unconsciousness whatsoever. The studies here presented enable us to understand this phenomenon. When a blow is struck to the head, two phenomena occur within the head: first, the deformation of the skull, with the subsequent waves traveling along the skull, and secondly, intracranial pressure waves traveling through the brain substance. Physicists state that compression alone does not cause alteration in nerve function. It is interaction of the forces produced by the intracranial pressure and the deformation of the skull which gives rise to the concussive phenomenon. The observations of Dr. Gurdjian do more than satisfy our scientific curiosity. He has shown us that in cranial concussion, there is no anoxia and there is little anoxia of any other portion of the brain unless contusion occurs. We know from other experiments that if anoxia develops in the blood cerebral edema will occur. So in the central nervous system, if there is any obstruction to the air passages, a pronounced cerebral edema develops, not due to the actual damage to the brain itself, but due to the generalized anoxia. It is therefore important, and a fact which is frequently overlooked, that the air passages be kept perfectly free of mucus and foreign bodies such as teeth, so that no such anoxia will develop.

Dr. E. S. Gurdjian, Detroit: Dr. Walker gave an excellent discussion on the mechanism of concussion. I think one other point that should be emphasized is that we are dealing with dynamic pressures, not static pressures. A hydrostatic pressure in an enclosed cavity such as the skull may cause no damage even if it were at high levels, but when dynamic pressure waves pass through the brain at speeds of $\frac{1}{1,500}$ second or less, shear and tear of tissue may take place in their path, and experimental and clinical work supports this concept.

WEIL'S DISEASE

Observations in Sixty-One Cases with Special Reference to the Use of Penicillin in Six Cases

H. M. PATTERSON, M.D
Olaa, Hawaii, T. H.

A complete discussion of Weil's disease will not be attempted in this paper. In a previous paper[1] I gave a general report of observations in 37 cases of Weil's disease, and another paper[2] now ready for publication reports observations in a larger series of 61 cases. Only such general considerations as are necessary to bring out points in the management and treatment of this disease will be discussed in this presentation.

To the average physician the term Weil's disease suggests infectious (spirochetal) jaundice, but since nothing like all patients ill with this disease show jaundice the newer term leptospirosis is probably preferable. However, due to common usage the term Weil's disease will be used throughout this paper. This disease is probably not nearly as uncommon or as severe in the Western Hemisphere as the medical literature indicates. An editorial in The Journal of the American Medical Association of Oct. 11, 1941[3] stated that only 67 cases of this disease had been reported in the American literature, with different writers reporting a mortality rate from 5 per cent to 40 per cent or about 30 per cent in cases with jaundice. In 1941 Larson[4] reported 51 cases from various parts of the United States and Puerto Rico, some of which may have been included in the 67 cases mentioned previously. Lester and his co-workers[5] in 1942 reported 14 cases; in 1943 Bruno and his co-workers[6] reported 15 cases, and in 1944 Patterson[1] reported 37 cases. A number of reports of smaller groups of cases have been made since 1941, but probably the total number of cases reported in the American literature is less than 300. Since the literature is made up of reports of a few cases from widely scattered areas it would be expected that 1 death would cause the mortality rate to appear unduly high; likewise, the physician treating an occasional patient would possibly not always institute the treatment program most likely to result in recovery. The latter point in my belief is certainly true, since I consider that the best single step in the treatment of the patient severely ill with Weil's disease is to give whole blood transfusions from donors who have recovered from this disease. Such transfusions would not be generally available, since so few cases are on record in the average community. In the 61 cases on which this report is based there was not a single death. I do not believe that this lack of mortality is due to any lessened virulence of the Leptospira icterohemorrhagiae in this area, because I have seen a death from this disease in a neighboring district and have had reports of other deaths in the Territory of Hawaii. Likewise 6 of the patients in this series were desperately ill, apparently to a degree similar to that of the patient in the average case outlined in the literature. Probably with a few exceptions, only the relatively small number of exceedingly severe cases are being diagnosed as Weil's disease, leading to the conception that the disease is both severe and infrequent. It is considered that the treatment instituted in the 6 severely ill patients of this series saved the lives of some of them and that the treatment given to the remaining 55 patients prevented some of them from becoming severely ill. Undoubtedly, one reason why such a large series of cases of Weil's disease can be reported with no deaths is the fact that most of the patients were mildly ill. Only because of my increasing clinical experience with the disease were their cases ever correctly diagnosed. It is felt that nearly all instances of anicteric Weil's disease are being diagnosed as influenza or some other disease and that the illness of many of those patients who become mildly jaundiced is never correctly diagnosed because of the lack of laboratory facilities, because the proper laboratory tests are not performed or because the patients recover and return to work before the laboratory tests are completed or repeated. No attempt will be made in this paper to discuss the merits of the various laboratory procedures used in the diagnosis of Weil's disease. The procedure I consider most reliable is a rising titer shown in microscopic blood serum agglutination tests on specimens taken at weekly intervals during the illness and in the convalescent period. Such a test was positive in each of the 61 patients of this series in dilutions of at least 1 : 300; in all but 5 patients the agglutination tests were positive in dilutions of 1 : 1,000 or higher, and in all the patients on whom the tests were repeated either there was a rising titer or the titer was extremely high (1 : 10,000 or higher) in all tests. All the agglutination tests were performed by Dr. J. E. Alicata of the Parasitology Laboratory of the University of Hawaii.

The blood serum agglutination tests are performed on the first, eighth and fifteenth days after admission to the hospital. Often the patient has been discharged and must return for the tests on the fifteenth day after admission. The tests are negative on the first day, usually show no titer or a low titer on the eighth day and show a high titer or an increasing titer on the fifteenth day. In leptospirosis due to L. icterohemorrhagiae these tests will always be positive with the procedure now being used in the Parasitology Laboratory of the University of Hawaii. If an infection should be due to other strains of the Leptospira, specific antigens must be used. As brought out in a general report[2] I consider that it is possible that occasional infections with other strains of the organism do occur in this area, but they are rare and not of practical importance in this report. With a laboratory test that is about 100 per cent efficient in the final diagnosis of Weil's disease, it is felt that this test should be used and relied on in preference to tests for Leptospira in the blood and urine or inoculation of laboratory animals with urine or blood or their concentrates. It is true that in the average infection in this area the patient is nearly well of his disease when the laboratory tests confirm the clinical diagnosis, or at least the patient has passed through the stage when early, adequate treatment will modify the disease. However, all other laboratory tests which are available, and which are less efficient, in a majority of cases are not positive until the golden period for institution of the proper treatment has passed, namely, the first few days of the illness. I believe and have tried to clearly report[7] that the diagnosis of Weil's disease should be made on the basis of the early clinical signs and symptoms and that treatment should be begun on the first day of admission to the hospital. If the clinician will have a highly suspicious frame of mind he can make this diagnosis on the first day. The average patient presents a picture of moderately severe influenza with decided conjunctival and scleral engorgement. If the clinician remembers just this much he will usually make the correct diagnosis. The ocular signs are the key to the diagnosis of Weil's disease in the early stage. In more detail, the average patient will have on admission generalized malaise, anorexia, headache (usually frontal), chills, generalized muscular tenderness and weakness (often severe in the calf muscles), a listless and toxic appearance and the classic ocular signs of decided conjunctivitis and scleritis. The eyes will appear soiled and will vary from pink to red with a cyanotic hue and with no discharge or secretions. In the average patient there will be no jaundice or bleeding or enlargement of the liver or spleen on admission. The temperature may be as high as 104.2 F. but will average 101 F., while on the average the pulse rate will be 91, the respiratory rate 22, the white blood cell count 11,704 with no significant differential change, the red blood cell count between 3.5 and 4 million and the hemoglobin 65 to 70 per cent, with the urine showing 1 plus albumin and no cells or casts. If this composite picture is kept in mind, with emphasis on the ocular signs and with attention being paid to the occupation of the patient, the diagnosis of Weil's disease can be made within a few hours after admission and treatment can be started at once. This point cannot be overemphasized. The final diagnosis is established by the blood serum agglutination tests on the fifteenth day.

Table 1.—*Length of Illness and Other Data, Broken Down According to Special Treatment Received; All Patients Received the Same General Treatment*

Special Treatment	No. of Patients	Day in Hospital Temperature First Dropped to Normal (Average)	Day in Hospital Temperature Remained Normal (Average)	Days in Hospital (Average)	Days from First Symptom to Discharge from Hospital (Average)
Entire series (as below)	61	4.2	5.5	12.08	15.28
No special treatment	44	3.8	6.0	9.00	12.16
Sulfathiazole ...	7	7.8	9.7	19.30	21.50
Sulfathiazole plus whole blood from donors who had not had Weil's disease previously	1	2.0	22.0	38.00	40.00
Sulfadiazine plus whole blood from donor who had previously had Weil's disease	1	4.0	31.0	35.00	36.00
Whole blood from donors who had previously had Weil's disease	2	7.5	7.5	18.00	20.00
Penicillin	6	4.17	5.5	9.00	12.28

Between Oct. 1, 1941 and April 16, 1946 61 patients with proved cases of Weil's disease were admitted to the Olaa Hospital at Olaa, Hawaii, T. H. All 61 patients came to the hospital for treatment of a clinical illness, and each presented signs and symptoms suggestive of Weil's disease, the diagnosis being confirmed in every case by microscopic blood serum agglutination tests with L. icterohemorrhagiae antigen. All the patients, except 1 who come from a bordering ranch, were residents of the Olaa district of the island of Hawaii, which has a population of 7,500. The entire treatment of the 61 patients was carried out in one hospital under my direction. The treatment regimen has evolved during the four and one-half years of this study, and it is not claimed that the final answer has yet been found.

TREATMENT WITH SULFONAMIDE COMPOUNDS

The first 3 patients of the series were so ill that it was decided to treat them with sulfathiazole, 1 Gm. every four hours, this being continued for from three to ten days. Thereafter, courses of sulfathiazole, 0.5 to 1 Gm. every four to six hours according to the weight of the patient, were given to 5 other patients for from three to ten days and sulfadiazine, 1 Gm. every four hours for two days, was given to 1 patient. All these patients grew progressively worse while receiving this medicament, and thereafter it was not used again. See table 1 for comparable data with other special treatment programs. It is only accurate to state that of the 9 patients who received a sulfonamide compound 6 were decidedly ill, and a longer hospital stay would normally be expected for them than for the average patient in this series. However, when the sulfonamide therapy was stopped in 3 of the more seriously ill patients and blood transfusions were given improvement was so prompt that it was felt that medication with the sulfonamide drugs had been of no value.

TREATMENT WITH BLOOD TRANSFUSIONS

After sulfathiazole had been discontinued in the second patient of the series it was decided to give him transfusions of whole blood. No donors who had been proved to have had Weil's disease were available, so other donors were used. Improvement was definite but slow after the first transfusion of 550 cc. of citrated blood, so two other such transfusions were given with slow but certain improvement. At this point it was decided that whole blood from donors who had had Weil's disease should be the best treatment in future severely ill patients. The early cases were grouped closely together and the patients were all so ill that it was felt too hazardous to complicate their convalescence by using them as donors. Specimens of blood from all patients were typed and were Kahn tested. Patient 28 of the series was desperately ill and lost 30 pounds (13.6 Kg.) during his illness. On the ninth hospital day he was given 500 cc. of citrated blood from a donor who had had Weil's disease fourteen months before and whose blood titer had been 1 : 30,000 on his recovery at that time; the titer was not determined again at the time when blood was taken. Patient 28 was bleeding from the mouth and nose, was vomiting all food and liquids and was desperately ill when the blood transfusion was given. Thereafter he did not vomit, had no bleeding, became alert and proceeded to get well. The change was prompt and dramatic.

---

[7] Patterson, footnotes 1 and 2

TABLE 2.—*Treatment of Six Patients with Penicillin*

Patient	Days Ill Before Admission	Jaundice	Bleeding Before Admission	Bleeding in Hospital	Penicillin Sodium Intramuscularly	Temperature (F.) on Admission	Hosp. Day Temp. First Reached Normal	Hosp. Day Temp. Remained Normal	Days in Hospital
56	6	Scleral, mild	Epistaxis	....	15,000 U. every 3 hrs. for 53 doses	103.6	7	7	9
57	1	....	....	Epistaxis	15,000 U. every 3 hrs. for 40 doses	104.0	7	7	10
58	3	....	....	Hemoptysis	15,000 U. every 3 hrs. for 48 doses	102.0	6	6	11
59	5	Scleral, mild	....	Epistaxis	15,000 U. every 3 hrs. for 32 doses	99.0	2	2	6
60	1	....	....	....	15,000 U. every 4 hrs. for 36 doses	104.0	2	6	9
61	4	....	....	....	15,000 U. every 3 hrs. for 48 doses	104.0	1	5	9

Patient 47 was desperately ill on the seventh day in the hospital and insisted that she was going to die. She was extremely toxic, her jaundice was deepening and she was vomiting everything taken orally. A blood transfusion was started, using as the donor a man who had had Weil's disease two months before and whose blood titer was 1 : 30,000 at the time of the transfusion. After receiving 300 cc. of citrated blood the patient had a severe chill, which lasted thirty minutes. Thereafter she felt better and ate her supper without vomiting. The following day she was given the remaining 250 cc. of the transfusion which had been started the preceding day. She had no chill and was laughing before the transfusion was finished; her temperature dropped to normal the same day and did not rise again. She ate heartily thereafter and said she felt that a miracle had happened to her. She went home six days later.

Patient 50 was deeply jaundiced on admission and was weak and listless. He vomited everything taken by mouth. His liver was enlarged, and he was spitting blood. These symptoms progressed, and on the third day he was given 550 cc. of citrated blood from his brother, who had had Weil's disease two years and one month previously and whose blood titer was only 1 : 100 at the time of the transfusion. The patient had a slight chill which lasted ten minutes immediately after the transfusion, and he vomited. Thereafter he felt better; his temperature dropped to normal within twenty-four hours and did not rise again. However, he was not discharged until eighteen days later because of the deep jaundice, which slowly faded, and because of the enlarged liver. He had no bleeding from the mouth after the transfusion.

Much is written of developing a serum or obtaining serum from biological houses for the treatment of Weil's disease. Walch-Sorgdrager,[8] Taylor and Goyle[9] and nearly every textbook discussing this disease emphasize this type of treatment. Patients with the disease need not only serum but red blood cells and all the constituents of whole blood. In this entire series the average lowest red blood cell count was 3,755,000 and the average lowest hemoglobin was 66 per cent. In those patients who were jaundiced the average lowest red blood cell count was 3,331,000 and the average lowest hemoglobin was 64.8 per cent. All the patients of this series have had their blood typed and Kahn tested and in my opinion constitute the best source of transfusion for the treatment of future severely ill patients with Weil's disease in this area. Several of them have given blood to patients with this disease in neighboring districts, with prompt improvement of the recipients. See table 1 for comparable data with other specific treatments. In consulting this table it should be kept in mind that the patients who received blood transfusions as well as those who received the sulfonamide compounds were the most severely ill patients of the series, in whom a longer hospital confinement would be expected.

PENICILLIN THERAPY

In February 1944 Heilman and Herrell of the Mayo Clinic[10] reported good results with penicillin in the treatment of experimental infections of leptospirosis due to L. icterohemorrhagiae in guinea pigs and suggested that this drug should be effective in the treatment of such infections in man. Augustine and his co-workers[11] in September 1944 after experimental use of penicillin in laboratory animals concluded that penicillin has a suppressive effect on L. icterohemorrhagiae in a highly susceptible host when given before the appearance of clinical symptoms. These workers did not expect it to be effective after the development of clinical symptoms. In March 1945 Larson[12] of the United States Public Health Service in a similar study with young Swiss mice found that penicillin had a definite therapeutic effect on the course of the disease when administered in the first forty-eight hours, but thereafter its effectiveness was materially decreased. He also treated a comparable group of mice with immune serum and found it equally as effective as penicillin.

[10] Heilman, F. R., and Herrell, W. E.: Penicillin in the Treatment of Experimental Leptospirosis Icterohaemorrhagica (Weil's Disease), Proc. Staff Meet., Mayo Clin. **19:** 89-99 (Feb. 23) 1944.

[11] Augustine, D. L.; Weinman, D., and McAllister, J.: Penicillin Sodium Therapy in Experimental Weil's Disease, New England J. Med. **231:** 358-359 (Sept. 7) 1944.

In line with these reports I have treated the last 6 patients of this series with penicillin, beginning on the first day of the illness in each case. Sodium penicillin dissolved in isotonic solution of sodium chloride was used intramuscularly (table 2). In none of these patients treated with penicillin were the liver or spleen enlarged. The temperature dropped by crisis in patients 58 and 59 and by lysis in the other 4. These 6 patients presented a clinical picture on admission corresponding to the average for the entire series. With 2 of these patients showing mild jaundice and with 1 showing epistaxis before admission and with 2 showing epistaxis after admission and 1 showing hemoptysis after admission, it might have been expected that 1 or 2 of these patients would have become much more severely ill than they did. It is definitely felt that penicillin therapy modified the course of the disease. Though table 1 shows that patients in the penicillin-treated group compare closely to those in the group receiving no specific treatment it is felt that on the average the latter were not as ill as the former.

GENERAL TREATMENT

Patients with Weil's disease should have good care by the nursing staff and close observation by the physician in charge. These patients need care similar to that given to patients with typhoid fever. The fluid intake must be watched closely and parenteral fluids given as needed; in this series parenteral fluids were required in 12 per cent of the cases. Attention to oral hygiene is necessary. The patient must be encouraged and reassured. Analgesics for the relief of headaches and generalized aches and pains should be used freely and in adequate doses, being required in 65 per cent of the cases in this series. Acetylsalicylic acid in 10 grain (0.65 Gm.) doses provides satisfactory relief of these symptoms. Twenty-two patients in this series required measures to combat constipation, enemas usually being used. Epistaxis was present in 33 per cent of the cases and required treatment ranging from ice compresses to postnasal packs. Vitamin K is given to all patients, 2 mg. by mouth daily, and if jaundice or bleeding occur 10 mg. is given daily hypodermically. Because of the almost constant anemia ferrous sulfate and extracts of liver are given by mouth. Capsules containing all of the vitamins are given in large dosages because of the generally poor intake of food and the great loss of body weight, which averaged 10.8 pounds (4.9 Kg.) in this series. Likewise, these patients need a liver-protecting and tissue-building diet, and in this series a high caloric, high carbohydrate, high protein diet has been used. Because the kidneys are potentially damaged and because the Leptospira does poorly in an acid urine, tablets of methenamine and sodium biphosphate, which contain 10 grains (0.6 Gm.) of each, are given every eight hours during the hospital stay and for one week after discharge. Other signs and symptoms which occur less frequently are treated as they arise. In general no treatment is required for the eyes during the acute phase of the illness, but attention should be called to the frequent ocular complications, principally iritis, iridocyclitis and uveitis, which require treatment as they develop from one month to one year or more after the acute illness. In from 20 to 25 per cent of the patients in this series such complications have developed.

PREVENTIVE MEASURES

In this series 51 of the 61 patients were cane cutters and most of the others were exposed to the hazards of the cane cutter. The answer to the mode of entry of the organism has not been found, but all such workers should drink only pure water, should protect their extremities and faces as much as possible from abrasions, should wash their hands thoroughly before eating lunch in the fields and should avoid rubbing the eyes or wiping sweat from the face with soiled hands. Measures that will destroy the rat and mongoose population of this area will probably cause the disappearance of Weil's disease. The development of a vaccine to be given to field workers in this area seems to be indicated. After release from the hospital the convalescent patient should be given methenamine and sodium diphosphate in large doses in order to help destroy the Leptospira, which are shed in the urine for many weeks.

SUMMARY

1. General observations of the management of 61 cases of Weil's disease are reported.

2. Sulfathiazole was used in 8 patients and sulfadiazine in 1 patient with no apparent benefit.

3. Three whole blood transfusions from donors who had not previously had Weil's disease were given to 1 patient, who obtained slow but progressive improvement after each transfusion.

4. Single transfusions of whole blood were given to 2 patients and two smaller transfusions to 1 patient, using donors who had previously had Weil's disease, with prompt and certain improvement in each instance.

5. Penicillin was used from the day of admission in the last 6 consecutive cases with apparently excellent results. None of these patients became severely ill, and their periods of hospitalization compare closely to those of the mildly ill patients of the series who received no special treatment.

6. The general measures for hastening recovery are outlined, and preventive measures are discussed.

CONCLUSIONS

1. All patients with Weil's disease are potentially dangerously ill and require the best of nursing and medical care of the type such as given to the patient with typhoid fever.

2. The use of transfusions of whole blood from donors who have had Weil's disease should be the sheet anchor in the treatment of the severely ill patient.

3. The administration of penicillin from the first day of hospitalization is recommended for all patients with Weil's disease.

4. The sulfonamide compounds do not appear to be effective against Weil's disease.

---

[12] Larson, C. L.: [illegible] Effect of Penicillin and Immune Serum in the [illegible] Leptospirosis in Young White Mice and in Ho[illegible] 60: 319-323 (March 23) 1945.

MYOMETRIAL PHYSIOLOGY AND ITS RELATION TO PELVIC PAIN

R. A. WOODBURY, M.D., Ph.D.
RICHARD TORPIN, M.D.
GEORGE P. CHILD, Ph.D.
HENRY WATSON, M.D.
and
MARIE JARBOE M.D.
Augusta, Ga.

Many factors contribute to the presence of pelvic pain during menstruation. Attention in the present paper will be devoted primarily to the myometrium, though the person as a unit must always be considered. The present knowledge concerning human nonpregnant uterine contractions is based on extensive investigations on experimental animals supplemented by careful clinical observations and uterine pressure records from control, pregnant and dysmenorrheal patients. Intrauterine pressure records from the nonpregnant human uterine were first obtained by Moir,[1] who observed during menses that contractions occurred every two minutes and developed pressures as high as 100 mm. of mercury. No pain but a feeling of heaviness and discomfort occurred when uterine pressures of 120 mm. of mercury were present. In patients with severe dysmenorrhea, pressures of 150 mm. of mercury were recorded and vascular pulsations disappeared at 120 mm. of mercury. Bickers[2] showed that high uterine tone is associated with primary dysmenorrhea and that reduction in tone is associated with relief from distress.

The literature contains many references to neurogenic and myogenic types of dysmenorrhea; and it is generally accepted that acetylcholine and histamine are agents which could produce these types. Yet drugs such as "trasentin" (the hydrochloride of diphenylacetylaminoethanol) and "pavatrine" (beta-diethylaminoethyl fluorine-9-carboxylate hydrochloride), which are excellent spasmolytics to animal tissues exposed to acetylcholine, histamine or barium,[3] often fail to relieve the distress of dysmenorrheal patients. Why? As the first step in answering this question, it seemed advisable to determine whether acetylcholine and histamine would produce uterine contractions and pain in human beings.

Methods.—Uterine activity has been investigated with the aid of pressure tracings and electrouterograms. Balloons fastened to short sections of ureteral catheters size 4 were placed in the uterus and cervix and then connected to optical manometers of high frequency.[4] The recording systems and balloons were filled with fluid so that transmission of uterine pressure changes to the recording device was accomplished by displacement of less than 0.01 cc. of fluid. Accurate tracings could be obtained with only 0.1 cc. in the balloon, though usually 0.2 to 0.5 cc. was placed in the cervical balloons and 0.5 to 1 cc. in the uterine balloons. Advantages which this method offered included: (1) the use of exceedingly small balloons, (2) a minimal amount of foreign object reaction within the uterus, (3) opportunity to use multiple balloons and (4) ability to obtain true zero pressures and to appreciate the amount of tone present.

Previous efforts[5] to evaluate uterine activity by means of electrouterograms have been of limited value. In the present studies an electrocardiograph of the Einthoven type was adapted to move the photosensitive paper at slow speeds. Silver chloride-coated silver electrodes were placed either in the uterus and cervix or on the anterior and posterior lips of the cervix or in various positions on the skin of the patient. Clinically useful electrouterograms could not be obtained with extrauterine electrodes[6] but were obtained from electrodes inserted into the uterus and cervix (fig. 1, tracings 1 to 4). Interpretation of the electrouterograms from 28 patients frequently has supplied confirmatory evidence for the pressure records, but additional investigations will be required before full interpretation can be firmly established.

Production of Dysmenorrhea.—At various times in the menstrual cycle, especially during menses, acetylcholine and histamine have been injected intravenously into 6 control patients and 6 dysmenorrheal patients in amounts which produced definite discomfort, such as flushing, headache, intestinal contractions and tachycardia. Even though some injections were continued over a ten minute period none of these patients experienced the typical pain or distress associated with her menses or showed appreciable change in uterine activity (fig. 1, tracings 1 and 2).

Next in our attempt to intensify the symptoms of the dysmenorrheal patients and to produce them in the control patients, posterior pituitary preparations were injected intravenously. "Pitocin" (N. N. R.), even in doses which caused definite uterine activity (3, fig. 1), did not bring about any distress. In fact many of the patients felt better. "Pitressin" (N. N. R.), even in doses which supposedly had much less oxytocic activity than that present in the dose of "pitocin" given to the same patient, produced decided distress, definite uterine cramps and pains, increased amplitude and frequency of contractions and elevation of the uterine tone (4, fig. 1). There were similar observations in all 25 patients receiving "pitressin." In fact this preparation intensified or produced all the symptoms which that particular patient had experienced during her troublesome menstrual periods.

These observations suggest that effective uterine antispasmodics should have definite anti-"pitressin" activity toward the uterus. Drugs such as "trasentin" and "pavatrine" do not possess much anti-"pitressin" activity.[6] This may account for the disappointing clinical results with these drugs after preliminary pharmacologic studies seemed to offer so much.

The "pitressin" and "pitocin" used in these investigations were purchased on the open market.

[6] Unpublished observations by this laboratory.

Comparison of 3, figure 1, with 4, figure 1, shows that some patients have had greater uterine activity after "pitressin" than after "pitocin" even though smaller doses of the former were injected. This confirms the observation of Moir.[1] Apparently bioassay methods for these preparations are unsatisfactory, since in these patients "pitressin" excited the uterus more than "pitocin" did. The fact that the onset of the stimulative action of the former was so rapid constitutes strong evidence that its uterine action was direct and not dependent on ischemia secondary to vasoconstriction.

Some dysmenorrheal patients experienced temporary relief after urination. It seemed reasonable that the relief might be caused by the partial emptying of the uterine contents during micturation. This suggested that the stretching of the uterus by the accumulation of clots and menstrual fluid and débris contributed to the distress of the patient.

The influence of stretching the uterus by distention of the balloon was investigated. Dysmenorrheal patients as a group tolerated less stretch than did control patients. Dysmenorrheal nulliparous patients tolerated from 0.4 to 5 cc. with an average of 3.5 cc., while control nulliparas tolerated from 3 to 7 cc. with an average of 5 cc. Factors which may have contributed to this low tolerance in dysmenorrheal patients included underdevelopment of the uterus, lowered pain threshold, greater uterine muscle tone and greater edema and congestion in the uterus. Parous patients as a group tolerated greater distention of the balloon. This may explain the disappearance of dysmenorrhea with the first pregnancy in some patients.

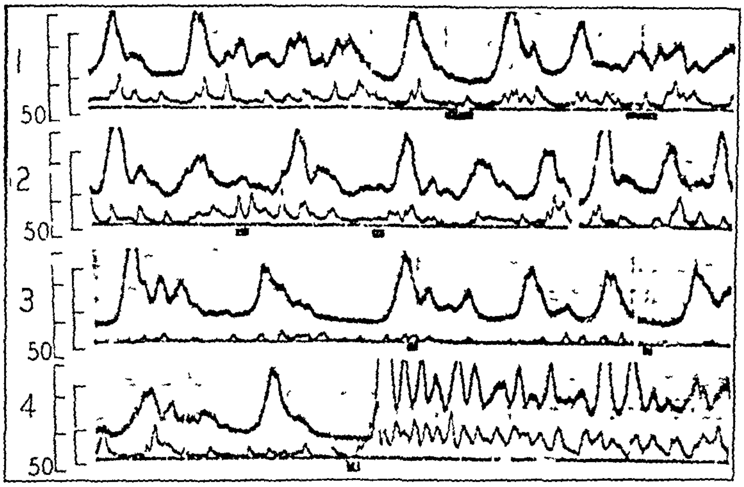

Fig 1 (tracings 1 to 4) —Pressure records and electrouterograms From above downward, tracings represent uterine pressure, electrouterogram, cervical pressure and base line interrupted at one minute intervals Pressure scale left uterine 50, 100, 150, 200 mm of mercury and right cervical 0, 50, 100 mm of mercury. These tracings, taken on the first day of menses when cervical biopsy indicated that ovulation had occurred, were secured from a patient who usually had slight but definite distress with her menses *Pronounced distress, but well within limits of tolerance, was induced by placing 3 cc.* of fluid in the uterine balloon and 0.5 cc in the cervical balloon Note that: (*a*) the uterine pressures are high (*induced by* placing 3 cc. of fluid in the uterine balloon); (*b*) the cervical and uterine pressures are not equal and the contractions may or may *not occur at the same time*, (*c*) the time durations of the cervical contractions are much shorter than those of the uterine contractions, and (*d*) electrical potential changes *occur during periods of* uterine activity

1 At each signal 9 mg of acetylcholine was injected intravenously in 1.8 cc of saline solution *Both injections, especially* the second which was more rapid, caused a flush, a smothering sensation in chest and cardiac acceleration from 70 to 90 and 110 per minute *The patient noticed no change in* uterine activity or in abdominal distress

2 At each signal 0.005 mg. histamine as histamine phosphate was injected intravenously. The patient noticed no change *in uterine activity or in* her abdominal distress, though she felt some fulness and throbbing in her head

3. At each signal 1 unit of "pitocin" was injected intravenously *The patient felt a* slight transient sense of warmth but did not experience abdominal distress.

4. At the signal, 1 unit of "pitressin" was injected intravenously. *This represents* less than 0.05 unit of oxytocic activity and supposedly less than one twentieth of the oxytocic substance injected while recording tracings in 3, figure 1. The patient *complained* of abdominal cramps and backache just like she had with her "bad monthly periods." After about ten minutes she felt about the same as before this last *injection. Note the* decided increase *in* uterine activity which starts *within 60 seconds* of the injection. Most of this time is required for circulation of the drug *from the cubital vein* to the uterus The fact that the onset of action is so rapid serves as strong evidence that the uterine stimulative action of this drug is direct and *not secondary to* uterine vasoconstriction

Pressure Records of Control and Dysmenorrheal Patients.—The balloons imitated clots and stretched the uterus, which caused increased uterine activity. No sharp line of demarcation could be observed between the uterine tracings of control and dysmenorrheal patients. However, definite differences were present. During menses in control patients contractions occurred once every 1.5 to 3 minutes and developed maximal pressures of 60 to 150 mm. of mercury. Between contractions pressures of 5 to 15 mm. were present, indicating good relaxation. The uniformity and regularity of the contractions as well as the good relaxation between contractions indicated that the uterus was contracting as a unit. It is suggested that these should be called well coordinated contractions. In 5, figure 2, tracings from a control patient show coordinated contractions. The phenomenon of summation and of a relative refractory period[7] are illustrated. In dysmenorrheal patients the contractions were the coordinated type with extremely high pressures (6, fig. 2), the poorly coordinated type with high pressures (7, fig. 2) or the uncoordinated type with low pressures (8, fig. 2). In the coordinated, extremely high pressure type, the uterine musculature contracted as a unit and pressures of 140 to 340 mm. of mercury were encountered Over a thirty minute period in 1 patient the pressures at the height of contractions averaged 230 mm. of mercury. These pressures greatly exceeded both those in the control patients and those of 40 to 90 mm. of mercury which are the limits of the maximal pressures developed by the uterus during parturition.[5] There is no doubt whatsoever that the pain of dysmenorrhea is real. It is not just psychic in such patients. The pressures between contractions were from 15 to 40 mm. of mercury in some patients and from 25 to 100 mm. in others. These uterine tone values were higher than the 5 to 15 mm pressures of the control patients

Uterine pressure pulsations corresponding in rate to the heart beat were observed in many patients. These pulsations frequently were reduced in amplitude or disappeared while the uterine pressure was elevated, but often they did not disappear even when the uterine pressure reached values much higher than the arterial pressure. Apparently, in some if not all patients these pulsations were transmitted directly from the throbbing abdominal aorta and did not represent pulsations of uterine blood vessels.

Contractions of short duration, which were generally not synchronous with contractions in surrounding portions of the uterus, have been named uncoordinated contractions. They frequently were superimposed on a background of coordinated contractions and at intervals they temporarily replaced them (fig. 3). When recordings were obtained for several hours poorly coordinated or uncoordinated contractions would become superimposed on the background of coordinated contraction in the control patients and would dominate the tracings of dysmenorrheal patients who originally showed just partial disorganization. Occasionally further distention of the balloon would bring about a temporary return of coordinated contractions.

[7] Rudolph, L, and Ivy, A C Coordination of Uterus During Labor, Am J. Obst & Gynec **21**: 65 82, 1931

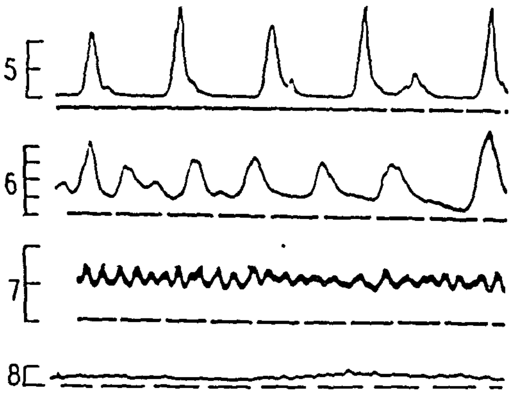

Fig. 2 (tracings 5 to 8).—Uterine pressure records from control and dysmenorrheal patients obtained on first day of menses. The base line was interrupted at one minute intervals. The pressure scale is in units of 50 mm. of mercury.

5. Uterine contractions from control patients are coordinated and good relaxation is present between contractions. The low tone between contractions and short periods of elevated pressure indicate that the balloon was in the lower uterine segment. A few accessory contractions occur. When these are present at the height of a contraction they elevate the pressure to abnormally high pressures. Only slight discomfort and no distress is present during these contractions.

6, 7 and 8. Tracings from 3 different dysmenorrheal patients: In tracing 6 poorly coordinated contractions are superimposed on coordinated contractions. Pressures are high during and between contractions. In tracing 7 poorly coordinated contractions dominate, indicating that incomplete tetany is present. The uterine tone is high and contractions fail to develop high pressure. However, the patient experienced much distress. In tracing 8 the pressures are not high yet the patient was experiencing severe pain while this tracing was being recorded.

The pressure at which patients complained of pain varied a great deal. When contractions were organized most patients complained of discomfort before pressures of 100 mm. of mercury were reached and of distress with pressures of 180 mm. of mercury. When contractions were disorganized and relaxation was inadequate, incomplete tetany (7, fig. 2) or complete tetany (8, fig. 2) developed. Under these conditions pain was present at pressures of 40 to 70 mm. of mercury. Extremely severe pain occurred while the tracing shown in 8, figure 2, was being recorded although pressures of only 20 to 30 mm. of mercury were present. It seemed advisable to determine whether such low pressures might be present in one part of the uterus while higher pressures were present at another level and were causing the pain.

Intrauterine Pressures in Different Parts of the Uterus.—Records were obtained simultaneously from three balloons inserted at different levels into the uterus and from one balloon inserted into the cervix. These tracings showed that the uterine pressure curves were different at various levels within the uterus both during coordinated contractions (fig. 4) and during uncoordinated contractions (fig. 5). Pain seemed to be present during uncoordinated contractions when pressures above 40 to 70 mm. of mercury occurred at any level within the uterus. As in the monkey,[9] uterine contractions are not peristaltic waves, in that no wave of relaxation precedes the contraction wave (fig. 4). Contractions may start in a region close to the juncture with the tubes,[8] yet the increase in pressure occurs first in the lower uterine segment and body of the uterus, then subsequently in the dome of the fundus. Downward from the dome of the fundus, the uterine muscles progressively contract faster and relax more completely. The musculature in the dome is slow to contract and even slower to relax (fig. 4). In menstruation as in parturition retraction of the lower uterine segment tends to occur. On the assumption that uterine contractions in labor and those in menstruation are similar, the records in figure 4 show that retraction of the uterus in parturition can be explained by the shorter contractions and the earlier and more complete relaxation of the muscles of the lower uterine segment as compared with those of the upper uterine segment.

The fact that different pressures exist in different portions of the uterus during menses allows coordinated contractions to propel clots and menstrual débris downward and to push arterial blood into the high pressure area of the dome of the uterus. The mechanisms by which these are accomplished and the influence of disorganized contractions on them will be described. When coordinated contractions occur during menses, relaxation brings about a large pressure gradient from the dome to the body of the uterus and from the body to the lower uterine segment (fig. 4, curves *A-B* and *B-C*). This means that débris is pushed downward within the uterus during the relaxation phase and not during the contraction phase. However, during the contraction phase there is a large pressure gradient between the lower uterine segment and the cervix, which moves débris into the cervix and thence into the vagina (fig. 4, curves *C-D* and *D*).

In patients with coordinated contractions, relaxation occurs between contractions and the strong uterine activity, though painful, will push débris and clots down and out of the uterus in the manner previously described. Contractions then may become reduced in intensity, and relief is obtained. In patients with disorganized contractions, relaxation between contractions is inadequate. Strong contractions develop sufficient pressure to clear the lower uterine segment but fail to

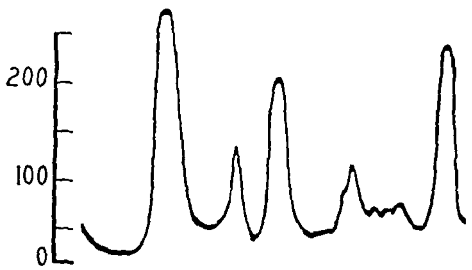

Fig. 3.—Uterine pressure record from patient with severe dysmenorrhea. This tracing is interesting in that the first contraction occurs after a period of adequate relaxation. Note the high pressure developed during this contraction. Severe distress was present during this contraction after the pressure was above 175 mm. of mercury and until it had decreased to 75 to 100 mm. of mercury. A short period of incomplete tetany at the right shows that poorly coordinated contractions were superimposed and replacing the coordinated contractions. Distress present during the period of incomplete tetany was severe but less so than that *at the height of the first contraction.*

[9] Ivy, A. C.; Hartman, C. G., and Koff, A.: The Contractions of Monkey Uterus at Term, Am. J. Obst. & Gynec. **22**: 388-399, 1931.

produce sufficient pressure to remove débris adequately from the body and dome of the fundus (fig. 5 and right half of fig. 4). Contractions continue, and dysmenorrhea of the type illustrated in 6, fig. 2, develops. This may continue, or the débris may be moved and relief obtained, yet in many of these patients there soon develop definitely disorganized contractions like those illustrated in 7, figure 2, or 8, figure 2.

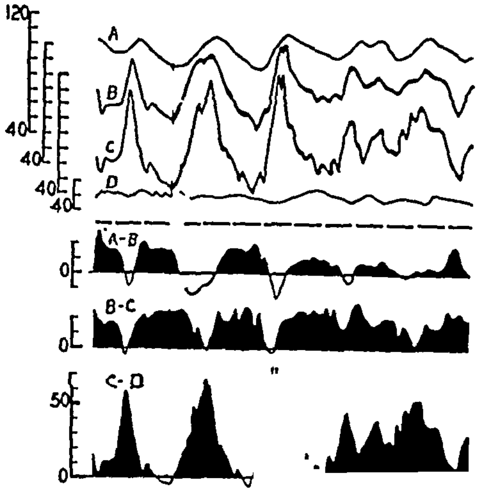

Fig 4.—Pressure records were obtained simultaneously from four balloons placed within (*A*), the dome of the fundus, (*B*) the body of the uterus; (*C*) the lower uterine segment, and (*D*), the cervix. The curves were replotted to the same pressure scale, with each curve lifted the amount indicated at the left in order to prevent superimposition of lines. The pressure increases in the lower uterine segment and lower portion of body of uterus start earlier, occur more rapidly and are shorter in duration than those in the dome of the fundus. Curves *A — B*, *B — C* and *C — D* are differential pressures which show the pressure gradients between the dome and body of the fundus (*A — B*), between the body of the fundus and the lower uterine segment (*B — C*) and between the lower uterine segment and cervix (*C — D*). These differential pressures are the pressures which influence the passage of clots and debris. The coordinated contractions at the left provide waves of propulsion even though the uterine tone is high. The poorly coordinated contractions at the right fail to supply a wave of propulsion. Note also that during the height of contractions the pressure in the dome of the fundus is lower than that in the body of the fundus. During this time the pressure gradient is reversed. (See negative pressure values on tracing *A — B*). To a slight extent this would interfere with outward propulsion of uterine content, but it facilitates blood flow from vessels in the body of fundus to vessels in the dome.

An interesting record was obtained in figure 5; the pain of the patient was intense and the contractions were disorganized in type. Uterine tetany was present and pressures in the dome and body of the uterus were low, while pressures in the region of the third balloon, located in the lower uterine segment, were high. This might well be called a constriction ring during menstruation or a spasm of the isthmus, or it could result from an exceptionally long cervix. It would definitely interfere with the downward flow of débris and could account for this patient's distress. The injection of "pitressin" produced extreme distress and caused intense disorganized contractions of muscles in the dome and body of the uterus but did not further elevate the high pressure in the lower uterine segment. The pressures in the dome and body of the fundus approached but still did not reach those in the lower uterine segment. Apparently the musculature of the isthmus was already near maximal disorganization and maximal contractions, while the muscles in the dome and body had developed some inertia secondary to fatigue and insufficient blood supply.

During coordinated contractions the slow and incomplete relaxation in the dome should interfere with the blood supply to this area because the pressure remains high in this area. In 1 patient pressure in the dome remained over 260 mm. of mercury for more than three hours. The blood pressure was 130 systolic and 90 diastolic. How did the tissues in the dome of the uterus obtain their blood supply? The following mechanism appeared to be responsible. Between contractions adequate relaxation occurred in the body of the fundus of the uterus and in the lower uterine segment, and arterial blood could flow into vessels in these areas. During contractions the pressures in these regions exceeded that in the dome by 30 to 40 mm. of mercury (fig. 4) and squeezed some arterial blood up into the vessels of the dome since the wave of contraction passes upward toward the dome.

In monkeys during uterine contractions the areas in the regions of the juncture of the tubes and uterus have been observed to show no blanching during uterine contractions.[9] In view of the observation that uterine pressures differ at different levels within the uterus, this localized lack of blanching in the monkey could be evidence that contractions of the uterus of the monkey also serve to facilitate arterial blood flow to all portions of the uterus.

Though myometrial activity is an important factor in the distress of dysmenorrhea, the amount of edema, congestion, vasoconstriction, tissue fragility, heightened tissue irritability and fibrinolysis of menstrual débris are also important physiologic factors.

SUMMARY AND CONCLUSION

Dysmenorrhea can be produced in control patients and intensified in dysmenorrheal patients by intravenous injections of small quantities of "pitressin" and by stretching the uterus or cervix. It could not be produced with intravenous injections of acetylcholine, histamine or "pitocin" in quantities which produced definite side actions.

In some patients "pitressin" has greater uterine stimulative action than "pitocin." Hence, the present bioassay method of these preparations is misleading.

Summation, relative refractory period and incomplete and complete tetany were observed in the human uterus.

Uterine pressures at which patients complained of pain varied a great deal. When contractions were coordinated, discomfort usually occurred at a pressure near 70 to 100 mm. of mercury and distress appeared near a pressure of 140 to 180 mm. of mercury. In the presence of incomplete or complete uterine tetany, pain always was severe at much lower pressures; usually severe pain occurred with pressures of 40 to 80 mm. of mercury.

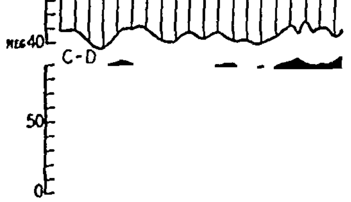

Fig 5.—Uterine pressure curve showing constriction ring during menses. The curves were obtained from use of multiple balloons and were replotted as in figure 4. Compare curves *C* of figures 4 and 5. Note that constriction rings seem to occur during menstruation. *The downward propulsion of* menstrual debris is prevented by the constriction ring.

Pressure records secured from different levels of the uterus showed definite differences. The shortest contractions were observed in the region of the cervix. The musculature in the dome of the fundus is slow to contract and even slower to relax. Downward toward the lower uterine segment, the musculature progressively contracts faster and relaxes faster and more completely. As a result uterine pressure levels are different at various levels within the uterus. Débris is pushed outward within the uterus during relaxation and not during contractions.

Disorganized contractions fail to propel menstrual débris downward within the uterus In some patients the disorganized contractions develop a constriction ring which further obstructs the outflow of débris.

It was found necessary to use intrauterine electrodes to obtain electrouterograms which showed a relationship to the uterine activity.

ABSTRACT OF DISCUSSION

Dr. M. Pierce Rucker, Richmond, Va No other organ in in the body is so capricious as the uterus There is a tremendous species variation in its behavior In the human being the least change in the environment of the uterine fiber makes a difference. The behavior of the uterus varies with the time of the menstrual cycle and with the stage of pregnancy. For instance, the response of the parturient uterus to posterior pituitary injection varies greatly according to whether it is given antepartum, intrapartum or postpartum Nor can one predict what the behavior of the intact organ will be, from the action of strips of isolated muscle Furthermore, different parts of the uterus behave differently This has been known to be true for the pregnant uterus for some time So far as I know this is the first time that it has been shown to be true for the nonpregnant organ. One might pursue this line of thought further by showing how certain drugs change the response of the uterus to other drugs. I mention this to show how important are careful studies on the intact uterus, such as the report which was heard today. I was interested to see that Dr. Woodbury and his associates' work confirms that of Bickers, who showed that increased tone between contractions was found in dysmenorrhea. They have gone further and shown that the nonpregnant uterus may contract in a regular orderly manner which they called organized contractions or in a disorderly or disorganized manner. The latter type is also associated with dysmenorrhea The orderly type, as I understood from the paper, is associated with dysmenorrhea only when the tone of the muscle is increased They demonstrated a constriction ring in a dysmenorrheic uterus. I have been interested in constriction rings in the parturient uterus for years. In labor such rings are found in the uterus that contracts in an irregular manner: another phenomenon which the parturient and the menstruating uterus have in common. I am not surprised that they found no effect from acetylcholine. I have tried this drug in uterine inertia without noticeable benefit. Perhaps the greatest surprise, aside from the demonstration of a constriction ring in a menstruating uterus, is that the nonpregnant uterus may contract with more force than the uterus in labor: And yet when one considers the relative thickness of the wall of the pregnant and nonpregnant uterus one should not be surprised. The authors are to be congratulated on their work.

Dr. A. R. Abarbanel, Beverly Hills, Calif.: I want to join with Dr. Rucker in congratulating Dr. Woodbury and his associates for an ingenious and remarkable piece of work. They have shown, along with Moir, that a uterine contraction leading to anoxemia of the uterine muscle can be associated with severe pain. I think that they might also have gone a little further and tried to duplicate the experiments of Robertson, who showed that by injecting sterile water in a tense nervous patient, spasmodic contractions of the uterus might result. Prolonged labor may be caused by what is considered to be myometrial dyskinesia or disorganized myometrial contractions. Clinically, it has been shown by several investigators that estrogen plays a distinct and favorable role in this condition. As a matter of fact, the effect of estrogen on the uterine muscle in disorganized contractions might be compared with that of digitalis on the heart in a similar condition. I would like to raise the question of the influence of various hormonal substances. For example, it has been noticed in hypertonicity of the uterotubal junction in the human subject that methyltestosterone sublingually in the form of "linguets" would abolish the spasm of the uterotubal junction as well as reduce the hypertonicity to normal values. In cases in which spasmodic dysmenorrhea was present, dysmenorrhea was usually relieved. It is believed that this hormonal substance acts directly on the myometrium. I too have found that the pattern of uterine contractions in the pregnant uterus during labor is essentially the same as that reported by Dr. Woodbury this morning. Further, I also found that the top portion of the corpus uteri contracts first and relaxes last, while the lower portions of the corpus contract last and relax first. As a result, it is clearly evident that the contractions of the human uterus in labor are patterned so that eventual expulsion of the fetus finally results.

Dr. William E. Hunter, Los Angeles: There are three factors that should be considered in the production of pain in dysmenorrhea: (1) the pain threshold; (2) the physiologic changes associated with ovarian activity, and (3) the sensory conditioning process. The pain threshold varies in different persons. As a rule women with dysmenorrhea have lower pain thresholds. They are more sensitive to painful stimuli during adolescence, reproductive life and the menopause. Ovulation produces certain physiologic changes, such as elevation of temperature, tissue edema, fragility of the blood vessels, irritability of the nervous system and muscular tension. All ovulating women feel these changes if they look for them. About 50 per cent are conscious of them, but only 5 per cent consult their physicians for relief. One only sees those patients who are somewhat incapacitated. The sensory conditioning process is a method of learning. By repetition one learns to read, and just so the dysmenorrheic woman learns to pick up subnormal stimuli and becomes sensitized to them. If an electrode is placed on the arm and the subject is instructed to break the circuit when pain is felt, after five hundred trials she will begin to feel pain when no stimulus is sent through the apparatus. If the experiment is repeated with stimuli above the pain threshold level, there is a conditioning to pain and in time the patient will complain of severe pain at the threshold level or even below. Is it not true that the perception and reaction to pain can be changed psychically by raising the pain threshold? I believe that many of the cures obtained by diverse types of treatments for dysmenorrhea are accomplished by suggestion. If the treatment is dramatic and the patient is led to believe in its efficacy either by injections or by dilation of the ureter, urethra or cervix, as I have done in many cases, the patient is relieved. She is temporarily cured by suggestion. For that reason I think that much of the work being done to relieve pain follows the old dictum, "Here is your trouble, now I remove it, now you are well."

Diphtheria in Partially Immune Persons.—It is probably a safe statement that the average American physician, who constituted the bulk of the medical corps since the days of mobilization, was initially not well acquainted with clinical diphtheria. His concept of the pharyngeal lesion was that of childhood diphtheria commonly found in textbooks. Diphtheria in partially immune persons, and accordingly that of many adults, is often somewhat different. During the course of the war this was probably first observed during a diphtheria epidemic in a prisoner of war camp at Aliceville, Ala. Here it was noted that "less than one third of the diseased throats were suggestive of diphtheria, while more than one half the lesions were, those of follicular tonsillitis."—Schulze, Hartwin A.: Diphtheria in the U. S. Army in Europe, *M. Bull.*, June 1947.

Special Article

TYPHOID IN THE LARGE CITIES OF THE UNITED STATES IN 1946

Thirty-Third Report

In conformity with the practice adopted in previous reports a communication was addressed to the health officer of each of the cities requesting the number of deaths from typhoid, excluding paratyphoid, both among residents and among nonresidents as recorded for 1946. The health directors of many cities keep no data on reallocations for residence, and this information can be secured only from the state health department, whose figures are not available until several months after the close of the calendar year. In some instances multiple inquiries brought forth irreconcilable replies. Too frequently the reporting of deaths is left to subordinate employees, and carelessness is evident. The health officer should give final approval to statistical data released by his department. A few health officers seem to have no knowledge of how many typhoid deaths have occurred in their community, and it becomes an increasing struggle to obtain accurate data. The possession of basic data seems paramount to the establishment and operation of an adequate local health service.

† One third or more of the reported typhoid deaths were stated to be in nonresidents.

For most of the cities of 100,000 population or more the Bureau of the Census has no estimates of population for dates since 1940. There are figures for a few of these cities, based on special censuses or sample censuses for various dates since 1940. Special censuses were conducted for Long Beach, Los Angeles, Oakland and San Diego in 1946. The Bureau of the Census has released a population estimate for Washington, D. C., as of July 1, 1946. Sample censuses were taken in 1944 for Detroit, Norfolk, Portland, San Francisco, Seattle and Tacoma. (A special census was taken in San Francisco in August 1945.) Estimates of the civilian population of counties are available for March 1 and Nov. 1, 1943, based on registrations for war ration books 2 and 4. Some of the cities (Baltimore, Denver, New Orleans, New York, Norfolk, Philadelphia, Richmond, St. Louis, San Francisco, Washington) are coterminous with their counties and the figures given in the releases are city as well as county estimates. Since for the vast majority of cities no official figures are available for any date subsequent to that of the 1940 federal census, it has again been deemed advisable to employ the populations determined by this uniform tabulation. For those cities for which special census figures are available, corrections in rates have been shown in footnotes. In most instances there are no or only minor changes in the rates. In no instance has any rate been extended beyond the first decimal point, and it is realized that this practice creates a slight disadvantage for the extremely large cities which now have but a single death from typhoid (Detroit).

third of the reported deaths were stated to have been among nonresidents. It is noteworthy that for the first time there is no city with a death rate in excess of 2.0, and thus the list of cities of second rank is completely omitted.

The number of cities with no typhoid death during the past two or more years has increased from twenty-five in 1941 and forty-one in 1945 to a new high of forty-nine in 1946 (table 9). Fort Wayne continues to head the list with no death in twelve years. Fall River and Lynn report no death in ten years, Cambridge no death in nine years Hartford, Springfield and Yonkers have clear records for eight years. South Bend reports no typhoid death among residents for eleven years.

The New England cities (table 1) (population 2,579,152) have set a new all time record with no deaths from typhoid in 1946. These cities have reported the lowest group rates in each of the quinquennial periods (table 13). The East North Central cities (0.06), although reporting a new low rate, must now be content with second place They were in first place in 1945 (0.07). The West North Central cities follow close behind (0.07) and nose out the Middle Atlantic cities (0.11). Only the Mountain and Pacific cities record a higher death rate for 1946 (0.31) than for 1945 (0.17). There have been but three deaths in the New England cities during the past three years, one in Providence in 1944, one each in Boston and New Bedford in 1945. While in 1940 one half of the eighteen cities which recorded no deaths from typhoid during a two year period were to be found among the New England cities, in 1946 only about one fourth (fourteen among forty-nine) were from this group The New England cities with a perfect record can do no better, but there is a tendency for other cities to attain the high standards set by this group.

Twelve of the large Middle Atlantic cities (population 13,129,185) (there were thirteen in 1945) report no death from typhoid in 1946 (table 2). Albany, Buffalo, Elizabeth, Erie, Jersey City, Paterson, Reading, Syracuse, Trenton and Yonkers have maintained their ranking of 1945 while Camden and Newark have been added to the honor roll. Rochester and Scranton, each with one death in 1946, were eliminated from the honor roll, Scranton after six years with no death. The Middle Atlantic cities have a group rate (0.11) which is but slightly higher than that of the East North Central and West North Central cities. It is much lower than the rate for 1945 (0.23) but not as low as that for 1943 (0.08). In 1946 there were fourteen deaths, thirteen among residents; in 1945 there were thirty, twenty-five among residents; in 1943 there were eleven, nine among residents. Jersey City reports no typhoid death for four years (table 9), Paterson and Reading none for five years, Albany and Trenton none for six years, Erie none for seven years, Yonkers none for eight years Utica records one death among residents in 1946, the second such death in fifteen years. It is stated that although the death occurred in a resident of Utica, the source of infection was reliably established as being in Italy. New York records eight deaths in 1946, all among residents (there were eleven in 1945, thirteen in 1944). The low mark was reached in New York in 1943 with four deaths, three among residents. (In 1942 there were five, all among residents.) New York reports a localized outbreak with 20 cases and no deaths in August 1946; the outbreak was attributed to fresh vegetables contaminated by sewage backed up out of a toilet bowl in an apartment immediately over the vegetable store. It is stated that in Philadelphia there occurred two deaths, both among residents. This marks a new low for this city. Pittsburgh records but one death, which occurred among nonresidents. Pittsburgh reported no death among residents in 1942 and again in 1946

The rate (0.44) for the South Atlantic cities (table 3) (population 2,727,985) is twice the low rate for 1944 (0.22) but is significantly lower than the rate for 1945 (0.62) In these cities there occurred twelve deaths in 1946 (nine among residents), seventeen in 1945 (eleven among residents), six in 1944 (three among residents). Five cities (Atlanta, Charlotte, Jacksonville, Miami, Richmond) are on the honor roll, and it is stated that the two deaths in Norfolk occurred among nonresidents. In 1945 Charlotte was the only city on the honor roll. In 1944 there were six such cities (Atlanta, Jacksonville, Miami, Norfolk, Tampa, Wilmington). Charlotte has been included in the group for the fifth time; however, for purposes of adequate comparison the figures for this city have been omitted in calculating rates for the group as a whole. Washington records six deaths in 1946, five among residents (there were two deaths in 1945, four in 1944, one in 1943) Tampa reports two deaths both among residents, Baltimore and Wilmington each one such death.

‖ 1945 special census gives rate of 1.1 for 1945 and 1.3 for 1941 1945 for New Orleans.

The East North Central cities (population 9,386,378) have lost first place, which rank they held in 1945 and back in 1941 and 1938. Fourteen (thirteen exclusive of Gary) of the cities in this group (Akron, Canton, Cleveland, Columbus, Evansville, Flint, Fort Wayne, Gary, Grand Rapids, Indianapolis, Milwaukee, Peoria, South Bend, Toledo) report no death from typhoid in 1946 (table 4). Gary was added to this group in 1940, but figures for this city have been omitted in determining rates for the group as a whole. The number of typhoid deaths decreased from seven in 1945 (thirty-three in 1940, thirteen in 1944) to six in 1946, a new low (the rate from 0 35 in 1940, 0.14 in 1944 and 0.07 in 1945 to 0.06 in 1946). Twelve cities (Akron, Canton, Cleveland, Evansville, Flint, Fort Wayne, Gary, Grand Rapids, Milwaukee, Peoria, South Bend, Toledo) record no typhoid death during 1945 and 1946 (table 9), Fort Wayne none for twelve years (the longest honor record of any city), Canton and Grand Rapids none for seven years, Evansville and Gary none for six years. Chicago records two deaths and Cincinnati, Dayton, Detroit and Youngstown each one death, all among residents. Detroit reports that among 24 cases of typhoid attributed to a church supper in a nearby community, 13 were in residents of Detroit among whom there occurred no deaths. A person preparing and serving food was found to be a typhoid carrier

¶ 1945 special census gives rate of 0.1 for 1945 for San Francisco

The six cities (table 5) in the East South Central group (population 1,286,747) show a decrease in the death rate (0.54 in 1946, 0.70 in 1945). However, a lower death rate (0.31) was recorded in 1944 and the same rate in 1942 (0.54). This group has the highest group rate for 1946, a position which it also held in 1945, the South Atlantic cities being next (0.44). The effect of hospitalizing patients from surrounding rural areas continues to be evident Of seven deaths in 1946, four were among nonresidents (seven of nine deaths in 1945). Two cities (Chattanooga and Nashville) report no deaths among either residents or nonresidents and appear on the honor roll The two deaths in Birmingham and the one death in Memphis were stated to be among nonresidents Chattanooga reports no death for five years (table 9). Knoxville records two deaths, one among residents; Louisville two deaths, both among residents.

4 No typhoid deaths in four years
3 No typhoid deaths in three years
# Forty seven without Charlotte and Gary

The West North Central cities (population 2,716,484) show a decrease in the number of deaths from three to two (table 6); one of the two was among residents. The death rate declined from 0 11 in 1945 (it was the same in 1943 and 1944) to 0.07 in 1946 Seven cities (Des Moines, Duluth, Kansas City, Kan., Kansas City, Mo, Minneapolis, St. Paul, Wichita) record no death, and St. Louis reports one death among nonresidents. After a period of four years (1941 to 1944) without a death, Omaha reported one death in 1945 and another in 1946. There has occurred no typhoid death in Duluth for the past eight years (table 9), none in

Des Moines for seven years, none in Minneapolis for five years, none in Wichita for four years. Kansas City, Mo., records no death among residents for five years.

The eight cities of the West South Central group (table 7) (population 2,048,692) report a continued reduction in the death rate (2.00 in 1940, 0.83 in 1943, 0.59 in 1945, 0.39 in 1946). The actual number of deaths decreased from twelve in 1945 (forty-one in 1940) to eight in 1946, the lowest of record. Of the eight deaths in this group of cities, two were among nonresidents (eight of twelve in 1945). The low point for deaths among residents (four) occurred in 1945. Three cities (El Paso, Oklahoma City, Tulsa) record no death in 1946. Tulsa reports no death for seven years. Dallas reports two deaths among residents. It is stated that of the two deaths each in Houston and New Orleans, one each was among nonresidents. Fort Worth and San Antonio record one death each among residents. Noteworthy is the reduction in the death rate of the cities of this group from 5.36 for the quinquennial period 1931 to 1935 to a new low of 0.39 in 1946.

The eleven cities (excluding Sacramento) in the Mountain and Pacific states (table 8) (population 4,186,039) report an increase from seven in 1945 to thirteen in 1946 (there were but five deaths in 1944). The rate has increased from 0.17 to 0.31. (It was 0.12 in 1944.) This is the only group of cities which records more deaths from typhoid in 1946 than in 1945. Sacramento has again been omitted in calculating the total number of deaths and the rates. This city reports one death among residents. Five of the Mountain

† Data for Fort Worth lacking.

†† 1940 census figures used.

and Pacific cities (Long Beach, Oakland, Salt Lake City, San Diego, Seattle) report no death from typhoid in 1946. There were nine cities on the honor roll in 1944, eight in 1945. Long Beach, Oakland, Salt Lake City and San Diego have maintained their ranking of 1945. Salt Lake City reports no death during the past five years, San Diego none for four years. It is stated that the one death in Spokane was among nonresidents. Of five deaths in Los Angeles, four were among residents. San Francisco and Tacoma each report two deaths, one among nonresidents. Denver records one death among residents.

THE HONOR ROLL

The number of cities with no death from typhoid has increased from fifty-six to sixty (table 11). Charlotte and Gary, not included in the group of ninety-three cities, also report no death. This is by far the best showing, and there remains no city with a rate of 2.0 or more. The number of cities with rates of less than 1.0 has increased by one (eighty-eight in 1946). Forty-seven cities (forty-nine with Charlotte and Gary) record no typhoid death in 1945 and 1946 (table 10). It is again emphasized that five cities (Birmingham, Norfolk, Pittsburgh, St. Louis, Spokane) in the first rank would appear in the honor roll were they not charged with deaths among nonresidents.

TABLE 13.—*Total Typhoid Death Rate per Hundred Thousand of Population for Ninety-Three Cities According to Geographic Divisions*

		Typhoid Deaths		Typhoid Death Rates				
	Population*	1946	1945	1946	1945	1941-1945	1936-1940	1931-1935

* 1940 census figures used

For the seventy-eight cities (table 12) for which data are available since 1910 there occurred fifty-four deaths from typhoid in 1946 (eighty in 1945, sixty-six in 1944 and seventy-eight in 1943). This provides a new low with a rate of 0.15 (the previous low was 0.18 in 1944). For the ninety-three cities the number of deaths in 1946 is sixty-two (eighty-seven in 1945 and seventy-three in 1944).

Table 13 shows the number of deaths for each of the past two years in each group of cities. It also shows the rates for 1945 and 1946 and the quinquennium 1941 to 1945 and the two preceding five year periods. It is hoped that the New England cities will continue to hold their unique record with no deaths and that other cities will soon find themselves in the same class. The continued reduction in rates for all groups is most impressive. For 1946 the health officers report only a few localized outbreaks of typhoid. Improvement has been general throughout the country, and typhoid as a cause of death in these cities is fast approaching the vanishing point. The war years do not appear to have contributed materially to the typhoid problem in the large cities.

Clinical Notes, Suggestions and New Instruments

THROMBOPHLEBITIS OF THE CAVERNOUS SINUS

Report of Complete Recovery in Case with Multiple Pulmonary Abscesses Complicating Pregnancy

EDWARD A. BRETHAUER Jr., M.D.
Pittsburgh

From a review of the literature it is evident that thrombophlebitis of the cavernous sinus is not a rarity. It has been reported in the literature since 1818,[1] and until recently it has been *98 per cent fatal. There have been reported instances of* recovery since 1869. Some of these recoveries have occurred spontaneously while others have been the result of surgical intervention, which has been a therapeutic procedure since 1902 *In all patients who were cured the convalescence was greatly prolonged.* Eagleton[2] reported a series of 25 cases in which there were 4 recoveries, in 3 of which the patient had surgical therapy. From the late nineteenth century until the onset of chemotherapy 58 recoveries have been reported.[3] The exact percentage of recoveries since the onset of chemotherapy is not available, but certainly reports of recovery are much more frequent in the literature.[4]

As far as the complications of thrombophlebitis of the cavernous sinus are concerned, there have been reports of meningitis, abscess of the brain, necrosis of the pituitary body and also of multiple cerebral infarcts.[5] Although it is likely that cases complicated by multiple pulmonary abscesses as a result of septic emboli have occurred, such reports are not available in American medical literature.

The etiology of thrombophlebitis of the cavernous sinus has been a subject of considerable discussion. There are usually *four ways of infection:*

1. Anterior foci of infection: These include the upper lip, alae nasi, vestibule of the nose and eyelids. The route of infection is by way of the angular, supraorbital and supratrochlear veins which drain into the cavernous sinus by way of the *ophthalmic vein.*

2. Internal foci of infection: The sources for this type of infection are the sinuses, turbinates and septum. This infection drains into the cavernous sinus by way of the sphenoid, ethmoid and ophthalmic veins.

3. Inferior foci of infection: The sources of this type are peritonsillar abscesses, operations on the tonsils, operations on the maxilla and deep cervical abscesses. These are carried by way of the pterygoid plexus or by direct proximal extension into the internal jugular through the lateral sinus and petrosal sinus.

4. Posterior foci of infection: These originate in the middle ear and mastoids. They extend from the lateral sinus through

the petrosal sinus. The most commonly observed cause for thrombophlebitis of the cavernous sinus is sinusitis, usually an acute exacerbation of a chronic sinusitis.[6]

There may be two forms of this disease. The acute form occurs as the result of a sudden occlusion. The second occurs as the result of a gradual occlusion, which allows for the development of collateral circulation. This type is usually not accompanied by the occlusive phenomena which accompany the former type. Both these forms are usually infectious in origin. The predominating organisms are either staphylococci or streptococci. It is possible to have a noninfective type of thrombosis of the cavernous sinus. This type occurs as the result of stasis of circulation due to some pathologic lesion which causes pressure on the cavernous sinus or trauma, such as a fracture of the basal portion of the skull.

From the point of view of pathology the lesion in thrombosis of the cavernous sinus is rather simple. As a result of inflammatory reaction the intima of the vein swells and slows the flow of blood, resulting in thrombus formation. The role of the pulsating internal carotid artery passing through the cavernous sinus must also be considered. This pulsation may aid in spreading the inflammation or infection and also may interfere with the flow of the blood, in that it may produce a to and fro movement.

The signs and symptoms occur usually as a result of occlusion or partial occlusion of the cavernous sinus and as a result of sepsis. There are usually pain in the orbit, headache, conjunctival edema, chemosis, ocular proptosis, dilatation of the retinal veins and partial to complete ophthalmoplegia. As a result of sepsis there are chills, fever, sweating, nausea and vomiting. One striking symptom which differentiates this condition from meningitis and other infections of brain or meninges is that the mentality is unimpaired until late in the disease.

The treatment consists in control of the infection and sepsis by means of chemotherapy and in an attempt to prevent thrombosis or at least to prevent the extension of a thrombosis. This is accomplished mainly by the use of anticoagulants. From recent literature it is apparent that combined treatment using the two foregoing principles is the most acceptable. However, cures have been reported in cases in which no anticoagulants have been employed. The case which I am reporting combined the use of anticoagulants, sulfonamide drugs and penicillin.

REPORT OF A CASE

Mrs. S. D., a 27 year old primipara three and one-half months pregnant, was admitted to the Elizabeth Steel Magee Hospital on Oct. 11, 1945 with chief complaints of severe headache, occipital pain, fever, moderate chills, nausea and vomiting. She was well until about two weeks before admission to the hospital, when there developed an infection of the upper part of the respiratory tract, for which she received symptomatic treatment at home. After the fifth day of the illness the headache became more severe and she began to have visual disturbances, nausea and vomiting. These symptoms continued for three days; then there developed a rather high fever with chills and increased sweating. At the same time the right eyelid began to swell and in several days the eye began to protrude and the lid became so swollen that the patient was unable to open the eye.

Physical examination at the time of admission revealed swelling and pronounced tenderness over the right frontal area, edema of the right conjunctiva with proptosis of the right eye. The examination of the fundi revealed blurring of the disk and dilatation of the retinal veins in the right eye. There were no significant observations in the left eye. There was a partial ophthalmoplegia of the right eye. There was definite evidence of sinus involvement, with purulent exudate coming from both nares. There was some swelling of the right occipital area but definite tenderness was absent. Examination of the ears revealed essentially normal conditions. The lungs were clear. The heart revealed no abnormalities. The heart rate was 110 to 120. The blood pressure was 130 systolic and 72 diastolic. Abdominal examination revealed a three months pregnant uterus. The reflexes were physiologic. The extremities showed no abnormalities. On admission the temperature was 100 F., but it soon rose to 104 F.

Heparin and penicillin were administered intravenously, and sulfadiazine was given by mouth. Attempts were made to keep the coagulation time between 12 and 15 minutes. Except for evidence of some involvement of the left eye, there was definite improvement during the first twenty-four hours of treatment. The temperature subsided to 101 F.; the leukocyte count dropped from 25,000 to 12,000 and the polymorphonuclear count from 92 to 78 per cent. Heparin therapy was continued for seven days. The administration of penicillin and sulfonamide drugs was continued for fourteen days, the patient receiving a total of 7,325,000 units of penicillin plus 1,080 grains (65.3 Gm.) of sulfadiazine. Four transfusions of 250 cc. of whole blood were given because of the rapid development of secondary anemia, which was probably due to toxicity and hemolytic staphylococci and streptococci.

After five days of intravenous penicillin therapy the patient had a generalized edema, became irrational and had an increased pulse rate and increased respiratory rate. Associated with this there was a moderate pulmonary edema and a gallop rhythm. The patient became comatose within the next twenty-four hours, after which she had a generalized convulsion. She was given two injections of 50 per cent magnesium sulfate, and all intravenous therapy was discontinued. She was given digitoxin because of the possibility of left ventricular failure. Within twenty-four hours she had a rather well defined diuresis; she became rational, and the pulmonary edema gradually subsided. There was a slow, continued improvement in the patient's general condition, and she was discharged on Nov. 5, 1945.

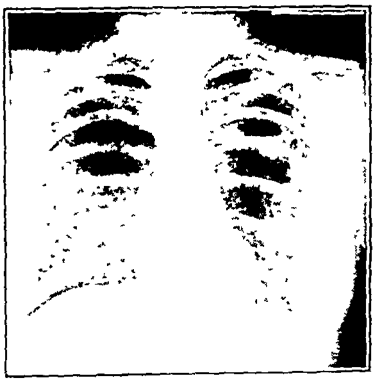

Fig. 1.—Multiple abscesses of the lungs

While the patient was hospitalized, roentgen examination of the nasal accessory sinuses showed a suppurative sinusitis of the left maxillary, frontal and ethmoid sinuses. There was no evidence of osteomyelitis. Blood chemistry studies were within normal limits. The Kahn test was negative. Urinalyses were normal except for slight albuminuria at the time of the high fever. Blood counts showed a rapidly progressive, secondary anemia and moderate leukocytosis with a shift to the left. One blood culture before chemotherapy was negative. The culture from the sinuses showed Staphylococcus aureus and hemolytic streptococci.

About one week after discharge from the hospital, following a treatment for her sinuses, the patient had frontal headaches, moderate fever and nausea and vomiting. She was readmitted on Nov. 16, 1945, at which time she was treated for an acute exacerbation of left frontal and maxillary sinusitis. She received 700,000 units of penicillin. At the time of discharge, Nov. 26, 1945, a second roentgen examination of her sinuses revealed no suppuration. There was evidence of only hyperplastic sinusitis of the left frontal and maxillary sinuses. During this period of hospitalization, there were no residual signs of the thrombosis of the cavernous sinus except for slight blurring of both nerve heads, more decided in the right eye.

The patient was free of symptoms except for a postnasal drip, which persisted for the next four weeks. She then complained of a chronic cough, which was paroxysmal and productive of a purulent sputum. These symptoms continued until Feb. 4, 1946 when the patient came to the office for an examination. Physical observations then revealed a patient, chronically ill in appearance, with a low grade fever, tachycardia, a slight purulent nasal discharge, increased tactile fremitus and crepitant rales over the lower lobe of the right lung. At this examination there were no residual signs of the thrombosis of the cavernous sinus.

---

[6] Jackson, C., and Jackson, C. L.: Diseases of Nose, Throat, and Ear, Philadelphia, W. B. Saunders Company, 1945, pp. 68-70.

A roentgenogram of the chest (fig. 1) showed pneumonitis with a small cavity in the lower lobe of the right lung and two cavities in the upper and lower lobes of the left lung. The cavity in the upper lobe of the left lung had a definite fluid level.

The patient was again admitted to the hospital on Feb. 25, 1946 and was given intensive penicillin therapy, for a total of 11,300,000 units. During this hospital admission she was delivered of a normal male infant that weighed 6 pounds 7 ounces (2,920 Gm.). Labor was induced by artificial rupture of the membranes, and the time of labor was twenty-one hours. The delivery was accomplished by pudendal block and a low midforceps application. Penicillin was continued post partum, and the patient had an uneventful postpartum course. At the time of discharge from the hospital, March 30, 1946, there were no abnormal physical signs on examination of the lungs, and a roentgenogram (fig. 2) showed a complete disappearance of all the cavities. There were only residual fibrous tissue changes in the right lower and left upper lobes.

COMMENT

This case is unusual and interesting in that it presents two disease states which were almost 100 per cent fatal previous to the onset of chemotherapy. Of course, the question of accuracy in diagnosis of thrombophlebitis of the cavernous sinus in such a case is always apt to be questioned. The physical observations in this patient were sufficiently definite to make the diagnosis fairly certain, but it was made even more definite by the development of embolic pulmonary abscesses. The distribution of these abscesses would certainly indicate that they were blood-borne and did not result from the drainage of infectious material from the sinuses. The absence of a positive blood culture does not rule this out. Only one blood culture was obtained, and this may have been obtained when there was no septicemia. Further blood cultures were not studied because of the extensive chemotherapy which this patient was receiving.

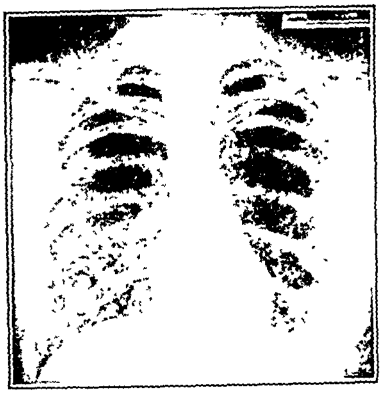

Fig. 2.—Complete disappearance of pulmonary abscesses

One outstanding feature of this case was the development of massive edema after five days of intravenous penicillin and heparin therapy. By calculating the sodium intake and observing blood studies, the role of possible excessive intake of sodium in producing this massive edema was ruled out. Other factors, therefore, were responsible for this edema. The effect of sepsis and toxicity on capillary permeability and nephritic function was a possible explanation; however, at the time of the edema the toxicity and sepsis had greatly abated. One must keep in mind the likelihood of an increased amount of posterior pituitary antidiuretic factor. This could have been associated with pregnancy, or it might have been influenced by the cavernous sinus disease. Because of the latter, the secretions of the pituitary may have been increased by irritation of the secretory cells as a result of either an inflammatory reaction or an impairment of circulation. More involved blood chemistry and water balance studies might have clarified the cause of the massive edema. In my opinion all these factors played a role and that of the antidiuretic factor should be emphasized.

The amount of penicillin used in this case was certainly extremely large. It was considered at the time that the patient was treated for the pulmonary abscesses that it would be advisable to use exceedingly large doses of penicillin because she had received moderately large doses to treat the thrombosis of the cavernous sinus. It was assumed that the same organism which caused the thrombosis was responsible for the abscesses and that possibly this organism might have developed some resistance to penicillin. This reasoning was prompted by the fact that septic emboli and pulmonary abscesses developed even though the patient was getting moderately large doses of penicillin during the time of the acute thrombophlebitis and for a long period after all signs of the thrombophlebitis had subsided. Therefore, the use of large doses of penicillin was justified.

SUMMARY

1. Recovery in a case of thrombophlebitis of the cavernous sinus with multiple pulmonary abscesses complicating pregnancy is reported.

2. A brief discussion of the case history and of pertinent clinical and therapeutic items in regard to thrombophlebitis of the cavernous sinus is included.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

The Council authorized the publication of a report [Report of the Council: Possible Dangers of Tetrathionate Therapy of Thromboangiitis Obliterans, J. A. M. A. **133:**693 *(March 8) 1947] advising against the clinical use of sodium tetrathionate because of the potential dangers of nephrotoxic actions as revealed in animals. Dr. Frank V. Theis takes exception to this caution, believing that there is no danger with clinical doses. Dr. Geza de Takats also has protested against the report. The Council believes that these letters should be published. They are reproduced here.* Austin Smith, M.D., *Secretary.*

Supplemental Report on Sodium Tetrathionate

April 4, 1947

Dr. Austin Smith, Secretary
Council on Pharmacy and Chemistry
535 N. Dearborn Street
Chicago 10, Illinois

Dear Doctor Smith:

I am concerned by the action of your committee in officially advising, in the March 8 issue of The Journal, that the "use of Tetrathionate in medicine should be abandoned" because of its nephrotoxic effect. To abandon the use of Tetrathionate, on the "substantial evidence" you present, would deprive many patients suffering with thromboangiitis obliterans, thrombophlebitis and other related diseases of intravascular clotting from what are believed to be the benefits of its use. Your conclusion is based on the results of a limited study with relatively large doses of the drug given experimental animals. It overlooks completely the clinical investigations and successful use of Tetrathionate as a therapeutic agent. I know of no report of toxic effect from the clinical use of Tetrathionate.

In 1936 Freeland and I were responsible for having Tetrathionate (Searle) prepared and made commercially available. I have used or supervised the use of more than 15,000 ampules of Tetrathionate supplied to me by G. D. Searle and Company and have been satisfied with the results in treating more than 500 patients. Confirming our observations, de Takats (*Surgery* **14:**661 [Nov.] 1943) stated that the "inexpensive and nontoxic sodium tetrathionate is now in routine use on our (his) surgical service" and that "clinically there can be no doubt about the beneficial influence of intravenous sulfur compounds especially in migrating phlebitis"; and "in the acute stages of Buerger's disease the intravenous use of sulfur has given surprising results." Allen, Barker and Hines in their recent book state that to their knowledge "no untoward reactions have followed the administration of sodium tetrathionate." It may be that the Council, carrying the weight and responsibility that it does to the medical profession, will wish to review its opinion in the light of further evidence on the clinical investigations with sodium tetrathionate as well as interpret the results of animal studies with the therapeutic doses used in clinical medicine. These doses have not been toxic.

The nephrotoxic effects of Tetrathionate which are cited followed the administration of relatively huge doses to experimental animals. For the dog, Chen, Rose and Clows reported the lethal dose as being 1.0 mg. per kilogram body weight or 140 times the therapeutic clinical dose, while Gilman determined the dose to be 250 mg. per kilogram or 36 times the clinical dose. Gilman's statement that "Tetrathionate is toxic to the renal tubule to a degree that moderate doses produce complete anuria within less than an hour" may be questioned from the data he presented. The "moderate doses" he used were excessively large (i. e. 11.0 Gm. in a single injection to a dog produced anuria in seventy-five minutes) and were toxic doses compared to our recommended clinical dose of 0.4 or 0.6 Gm. for an adult weighing over 70 kilograms. His report showed that with 7 times the human dose given rabbits and 16 times the human dose given dogs, none of the animals died and there were no demonstrable toxic or ill effects. There are few systemic therapeutic drugs of value which have a greater factor of safety than Tetrathionate.

Prior to our clinical use and investigations of Tetrathionate, we too studied the toxic effects on rabbits. Series of rabbits were given daily intravenous doses of 0.1, 0.2, 0.4 and 0.6 Gm. of Tetrathionate, which were equivalent to 9, 18, 36 and 72 times respectively the clinical dose per kilogram recommended for therapeutic use. Daily injections of 0.4 Gm. (35 times the clinical dose) for three days (total of 1.2 Gm.) resulted in death of the animals from twelve hours to three days after the third dose. Autopsy study revealed edema and necrosis of the liver, kidney, heart and other organs. Rabbits given the 0.1 Gm. dose (9 times the clinical dose) daily for twelve days (total of 1.2 Gm.) showed no ill effects, thrived and gained weight. Autopsy study revealed no evidence of nephrotoxic or any other toxic effect. Studies on these animals included blood and platelet counts, hemoglobin, blood clotting time and glutathione, fibrinogen and prothrombin contents. Even with the fairly large doses used in the latter series of rabbits we found no deleterious effect.

The clinical dose which we recommended after extensive clinical and animal investigations with various size doses is 0.4 or 0.6 Gm. of sodium tetrathionate. This is equivalent to an average of 7 mg. per kilogram, a really small fraction of the toxic doses used in the investigations by Gilman. Even our most intensively treated patients show no evidence of nephrotoxic or other toxic effects; some of these have been followed for ten years and have received more than 300 injections. Occasionally, transient reactions with faintness, nausea, abdominal discomfort or weakness have followed an initial or too rapid injection. However, the same reactions occur with the use of sodium thiosulfate. Prompt relief is obtained by the ingestion of milk, food or water. Smaller subsequent doses or slower injection will almost always prevent recurrences of these reactions.

Our clinical investigation during the past ten years has included laboratory studies on the urine, blood cell counts, clotting time, sedimentation rate, basal metabolism rate and determination of the blood cholesterol, lipids, fatty acids, phospholipids, nonprotein nitrogen, urea, protein, creatinine, glutathione, sugar, calcium, potassium, sodium, prothrombin and oxygen and carbon dioxide capacity and content (saturation) of the arterial and venous blood. The results of some of these studies have been published and are available in the surgical literature (*Arch. Surg.* **38**:191 [Feb.] 1939; **40**:190 [Feb.] 1940; *Surgery* **11**:101 [Jan.] 1942; *Ann. Surg.* **113**:1107 [June] 1941). When changes followed injections of Tetrathionate they were usually favorable for the continued use of the drug; no deleterious effects have been observed.

My own analysis of Gilman's reported observations is that (1) Tetrathionate, when used in doses comparable to those used clinically, is not toxic to experimental animals and (2) the conversion and elimination of the Tetrathionate from the body are much slower than for the thiosulfate solution. However, the delay in eliminating the drug in the body is not sufficiently prolonged to produce deleterious or toxic cumulative effect from daily injections and is the reason for our original decision, ten years ago, for substituting the tetrathionate for the thiosulfate solution. We arrived at the same conclusion from the results of studies on the elimination of the sulfur in the urine. This part of the investigation was done with the cooperation of Dr. Andrew McNally, toxicologist, who originally suggested the use of Tetrathionate.

In view of the benefit which so many patients with thromboangiitis obliterans, thrombophlebitis and other diseases with tendency for intravascular clotting have received from the therapeutic use of Tetrathionate (Searle) and in the absence of any clinical or laboratory evidence of toxicity in the doses we advise, it would appear that the Council should review all the information available and reconsider its recommendation that the "use of Tetrathionate in medicine should be abandoned."

Yours truly,

Frank V. Theis.

Dr. Geza de Takats of Chicago also has written as follows under date of April 7, 1947:

I have delayed giving you my reaction to the statement made by your committee regarding tetrathione because I wanted to study the article of Gilman and also look over our records regarding any untoward results with the drug.

Obviously, sodium tetrathionate as used in Gilman's experiments was being used in a dose about thirty-five times the dose used in patients. I might say that our group has never made any renal function tests before and after use of sodium tetrathionate in man. However, with the exception of dizziness, flushing of the face or short attacks of nausea which may follow any intravenous injection, no harmful effects have been obtained.

My assistants and I use tetrathione rather sparingly and certainly have made no such extensive use of it as has Dr. Frank Theis and his group. However, if your committee based its opinion on the data available from Gilman's experiments, very few potent drugs can be used at present.

If you gave a dog or rabbit thirty-five times the dose of prostigmine, mecholyl, heparin, dicumarol and many others, there would be widespread toxic damage and mortality among the animals.

Certainly the quoted experiments do not reproduce clinical conditions and I am writing to suggest that the committee review its statement and if necessary conduct some more experiments based on controlled clinical material.

No nephrotoxic effects were observed in the patients treated by Dr. Theis and his associates and apparently these investigators feel that there is little if any danger of such effects from the doses that they have used clinically. However, when an agent is capable of interfering with the important but insufficiently known SH functions, a word of caution is not amiss. It should be realized at least that the dosage must be kept at a minimum and the renal function kept under close observation. Further observations may reveal additional valuable information.

Council on Foods and Nutrition

ACCEPTED FOODS

The following food, dehydrated tree-ripened flaked banana, used primarily in the feeding of infants and small children, has been accepted as conforming to the Rules of the Council on Foods and Nutrition of the American Medical Association.

James R. Wilson, M.D., *Secretary.*

PREPARATIONS USED IN THE FEEDING OF INFANTS.

Kannenglesser & Company, New York

Kanana Banana Flakes.

Analysis (submitted by manufacturer).—Moisture 5.52%, ash 2.83%, fat (ether extract) 1.30%, protein (N × 6.25) 6.87%, carbohydrates, reducing 32.50%, sucrose 41.00%, starch 4.96%, total carbohydrates other than crude fiber (by difference) 83.48%.

Calories.—3.83 per gram; 109 per ounce.

Vitamins and Minerals.—	Per Hundred Grams
Vitamin A	154 U. S. P. units
Thiamine	0.199 mg.
Ascorbic acid	36.00 mg.
Riboflavin	0.318 mg.
Phosphorus	110.00 mg.
Magnesium	135.00 mg.
Sodium	406.00 mg.
Iron	2.70 mg.

RHEUMATIC FEVER CONTROL PROGRAM

The most comprehensive plan now in existence for control of rheumatic fever is probably that of the London County Council Rheumatic Scheme. School children in London are examined by school medical officers whose function is generally diagnostic. These doctors become especially interested and proficient in the recognition of rheumatic manifestations among the children routinely examined. General practitioners are invited to cooperate with the central office or one of its supervisory centers by referring to them children with diagnosed or suspected rheumatic fever who, in their opinion, should be admitted to a hospital. The London County Council has at its disposal 1,000 beds. When the central bureau passes on the case and the patient is approved by the medical referee the child is then transmitted by ambulance 20 miles to Carshalton or one of the other similar institutions in the country. These institutions, according to Parkinson,[1] are more than convalescent homes; they are probably best described as Hospital Schools. They have country surroundings with large open terraces alongside the wards onto which the beds can be easily run. It is the custom to carry out what is, in fact, open air treatment except in the most severe cases. Experienced medical officers believe that if the children are warmly clad there is no additional risk of infection or chill, that appetite is improved and sleep is sound. In severe carditis stress is placed on complete immobilization and ample nursing facilities. The children receive regular school instruction beginning with their convalescence from teachers appointed by the Ministry of Education. Parkinson stresses that education of rheumatic children is of great ultimate importance apart from the fact that the lessons help pass the time agreeably. The usual length of stay in one of these hospital schools is from six to twelve months.

The city of London has twenty supervisory centers distributed throughout, including the most thickly populated areas; ten of these are in connection with the outpatient departments of large hospitals. These centers carry out periodic supervision especially of patients discharged from the hospital centers, diagnose cases referred and instruct parents in child welfare. After school age young people with permanent valvular conditions are transferred to ordinary hospital outpatient clinics. Suitable employment is arranged for them by voluntary health societies such as the After-Care Association. The London City Council maintains a register of medical records and a card index of all the rheumatic children, past and present, who have been accepted at any center or hospital school. In 1938 the Council registered 22,800 children up to the age of 15 in London who were suffering or had suffered from rheumatic infection. This number represented an incidence of about 2.6 per cent of the child population.

With the passing of the New Health Act the whole of the health services and all the hospitals in the country will come under the control of the Ministry of Health in 1948; fourteen regions have been demarcated. They will be administered by regional councils, each working as far as possible from a main university center. The Royal College of Physicians appointed a rheumatic fever committee on which are represented the College, the Ministry of Health, the University of London, the Medical Research Council and the London County Council, with cardiologists and pediatricians concerned in the problem. This body is at present consultative, but it is believed that in the immediate future it will take the initiative in planning for a resumption of schemes like the London County Council scheme not only in London but in each of the regions into which the whole country has now been divided. The most urgent and the most difficult problem in connection with the control of rheumatic fever is the provision of sufficient beds for long term treatment of the rheumatic children.

In the United States public measures for the control of rheumatic fever are largely a matter of state and private concern rather than that of the governmental agencies. A good example of a state program is furnished by California. The program began with the formation in 1926 of the California Heart Association, the function of which is to arrange postgraduate education in heart disease for the physicians of the state. According to Rosenblum[2] the interest of physicians and of the general public was stimulated by the rheumatic fever program in Solano and Contra Costa counties. The program was supported by the state department of public health with funds made available by the Children's Bureau. Over 300 cases of rheumatic fever and rheumatic heart disease were detected and provision was made for hospital and convalescent care for many of them. Yearly symposiums open to all physicians in California and neighboring states were held in San Francisco, Los Angeles and San Diego under the sponsorship of community heart associations. These functions have been correlated by the California Heart Association and assisted by the medical schools and leading hospitals of the respective areas with teaching ward rounds, clinical demonstrations and lectures. In 1943 the California Tuberculosis and Health Association joined forces with the California Heart Association in forming a Heart Division of the California Tuberculosis and Health Association. This Heart Division provides an opportunity for health education and community organization in the field of rheumatic fever and rheumatic heart disease. Case registers for rheumatic children are being developed in San Francisco and Los Angeles counties. Although rheumatic fever and rheumatic heart disease are legally reportable in California, an adequate definition of the magnitude of the problem according to Rosenblum must await complete and effective reporting on a statewide basis. Here as well as in England the greatest shortcoming in the carrying out of the program is the lack of hospital and convalescent facilities. This shortcoming can be rectified by legislative action which will provide funds to assist local communities in developing programs and facilities.

THE PROBLEM OF AMEBIASIS

Albright and Gordon[1] point out that a considerable reservoir of unsuspected and unreported amebiasis has been brought back to the United States by the returning armed forces. The overall incidence of this type of infection in the United States is probably about 10 per cent. The so-called healthy carrier is a most important epidemiologic problem. Contrary to the widespread belief that Endameba histolytica may live and multiply within the lumen of the bowel without producing lesions or that an avirulent strain exists, they feel with Hargreaves[2] that the term "cyst carrier" is to be deprecated because every person who passes cysts must have vegetative amebas living on the tissues of his bowel wall and completing their normal development. Infection with the parasite always means invasion of the tissues with the production of pathologic lesions; cysts from asymptomatic carriers are fully pathogenic. Faust[3] demonstrated in dogs that there is no detectable difference in susceptibility to human strains of an acute, chronic or carrier type. The evidence concerning the inability of the parasite to live in the lumen without producing lesions is quite conclusive. Faust[4] in a series of 202 postmortem examinations conducted on accident cases in New Orleans found thirteen infections of E. histolytica demonstrated by the recovery of the organism in the bowel. The intestinal lesions consisted of pin point ulcerations, shallow crater-like lesions and rather extensive, superficial erosive processes of the mucosa. Amebas were demonstrated in each of these types of tissue involvement. These lesions represent the mildest type of damage to tissues reported in carriers and lend support to the belief that E. histolytica lives at the expense of the asymptomatic host. Albright and Gordon noted that amebic hepatitis develops in roughly one third of the patients who have never experienced diarrhea or dysentery. This strongly suggests that the "carrier" state is a pathologic condition warranting the same serious attention accorded other forms of the disease, since hepatitis is always secondary to invasive lesions of the wall of the bowel. The "carrier" represents an active stage of the disease, often completely free of symptoms, and for this reason the most easily overlooked and neglected. In this stage of the disease the opportunity is greatest for prevention of serious and even fatal complications.

Diagnosis of amebiasis is made by the case history, physical examination, proctoscopy, examinations of stools and only occasionally roentgenologic examination. Proctoscopy can provide invaluable information. Of special importance here are the color of the mucosa and the presence of bleeding points plus mucus, edematous areas and ulcerations. Early diagnosis of amebic hepatitis permits cure by medical means alone. The treatment includes a full course of emetine hydrochloride amounting to 0.65 Gm., with full courses of either carbarsone, chiniofon or diodoquin. Small abscesses will probably respond to this therapy, while larger abscesses require aspiration.

The aim of specific therapy is eradication of all parasites from the host. This is best accomplished by resorting both to emetine and to the enteric drugs, one having its action on parasites within the tissues and the other on parasites within the lumen of the bowel. Emetine hydrochloride given parenterally acts solely on trophozoites within the tissues. It leaves relatively untouched the trophozoites and cysts outside the tissues in the lumen or on the surface of the bowel. The enteric drugs, such as chiniofon, diodoquin, vioform and carbarsone, act on trophozoites and cysts of the second group within the lumen of the bowel. Albright and Gordon emphasize that the same therapeutic principles should be applied for all forms of amebiasis regardless of the phase of symptomatology. In Hargreaves' experience penicillin has proved life saving in severe refractory cases due to secondary bacterial infection. An attack on invading bacteria with penicillin and succinylsulfathiazole produced a dramatic improvement in these cases and made them more amenable to specific antiamebic treatment.

Current Comment

EXPERIMENTAL INSOMNIA

Tyler reports[1] experiments on insomnia involving 600 subjects at the California Institute of Technology. Up to 112 hours of sleeplessness, no significant physiologic or biochemical changes were produced, except in the electrical activity of the brain. Little variation from the normal was noted in the blood sugar, hemoglobin, blood cell count, body weight and temperature. The excretion of total nitrogen and creatinine, ketosteroids, and the level of adrenal-like substances in the blood were little affected. The slight changes in blood pressure, respiration and heart rate that occurred could be attributed to the state of relaxation of the sleepy subjects. The psychologic disturbances were the most obvious changes that occurred. The alterations in behavior which were first noticed between thirty to sixty hours of sleeplessness were characterized by loss of memory, increased irritability, inattention and hallucinations or illusions. While in the majority of subjects these disturbances were mild, in some there were symptoms resembling those of acute schizophrenia. The only effects on psychomotor performance found were those that indicated reduced ability to maintain sustained effort and performance.

NEW EPIDEMIOLOGIC PROBLEMS

In discussing epidemiologic problems arising from human action in an instructive lecture titled "Epidemiology Today," Professor Burnet's[1] first example is infectious jaundice or hepatitis associated with the vaccination of American troops against yellow fever using vaccine containing small amounts of normal human serum. Infectious jaundice has appeared also after the use of syringes in the injection of penicillin and other medicines without thorough sterilization of the syringes between injections. The virus of one type of infectious jaundice may be in the blood of symptomless persons, and it can survive various procedures. Burnet's second example "of large-scale epidemiologic happenings produced by human action that was designed to prevent disease" is the development of strains of pathogenic organisms, particularly streptococci, which resist the action of sulfonamides and other drugs. In 1944 the recruits in many U. S. naval training camps were given sulfadiazine daily for some months in order to prevent streptococcic infections. The results were not satisfactory, as an unduly large number of such infections occurred. Two streptococcus strains (types 17 and 19) had acquired resistance to the action of sulfadiazine and infected persons who were receiving sulfadiazine for prophylaxis just as readily as virulent normal strains caused infection in unprotected persons. Fortunately the sulfonamide resistant strains remained sensitive to penicillin. Burnet likens the appearance of a drug resistant bacterial strain to the emergence of a new animal species. The events in naval training camps warn against subjecting a community or other large group to long continued chemoprophylaxis. Burnet also warns against dangers in far flung treatment of gonorrhea with a single drug. New and drug resistant strains of gonococci may become dominant, as in fact is illustrated by the sulfonamide resistant gonorrhea.

THE FIRST ARTIFICIAL SPRING LEG

Teele[1] comments historically on the accomplishments of two ingenious citizens of Milton, Mass., one Mr. Benjamin Crehore, the other Capt. Lewis Vose. In 1798 Crehore began to manufacture bass viols, the first made in this country. In 1800 he made the first pianoforte manufactured in this country. His ingenuity was further challenged by the appearance in Milton of Dean Weymouth, a young man who had lost a leg in the service of his country. Crehore conceived the idea of making a wooden leg for him with joints in the knee, the ankle and the foot. After many modifications he succeeded in fitting out an artificial limb which worked easily. Capt. Lewis Vose, a saddler, arranged and put in the straps to secure the leg in place and the padding to make it work with comfort. History further relates that Mr. Weymouth used the artificial limb for a long time but, failing to obtain the money to pay for it, was obliged to return it to Mr. Crehore. Subsequently the leg disappeared from where it had been deposited and its fate is unknown. This artificial limb was believed to be the first of its kind made in this country. To confirm the claim to priority of invention, a statement of the facts in the case has been inserted in the Boston *Transcript.* A year has elapsed without response; apparently the claim to priority holds good.

MONGOLISM AND INFECTIONS IN PREGNANCY

Mongolism is a congenital but not hereditary general maldevelopment the cause of which is not known. The discovery by Gregg and others in Australia that maternal rubella in pregnancy may be followed by congenital cataract as well as cardiac and other malformations in the child led Ingalls and Davies[1] to look into the question of intercurrent maternal infections in pregnancies which produced mongoloid children. In a preliminary note they record 7 such cases, one each of influenza, rubella, mumps, mastoiditis, pleurisy, "grippe" and otitis media with sinusitis. The fact that in 6 of the 7 cases the maternal infection occurred at about the second month of pregnancy is, as they say, "provocative." This note should stimulate physicians to furnish data to determine whether there is a definite correlation between maternal infection in pregnancy and mongolism. Whatever the outcome of such analysis may be, the relations of maternal rubella to malformations in the fetus demand that everything possible be done to exclude maternal infections in pregnancy.

ORGANIZATION SECTION

Official Notes

GROUPS OF CLINICIANS TO AID SICK IN U. S. POSSESSIONS

Secretary of the Interior Krug recently requested the American Medical Association to appoint an advisory committee to select teams of competent clinicians to go for a short period to such places as Alaska, the Western Indian reservations, Puerto Rico and the Virgin Islands to aid the local physicians in the diagnosis and treatment of difficult cases of illness and to conduct clinics for the indigent with the view to provide a high grade of medical service. The advisory committee appointed comprises the Executive Committee of the Board of Trustees of the American Medical Association, Dr. George F. Lull, Secretary of the Association, Dr. Morris Fishbein, Editor of The Journal, and Dr. W. A. Morgan of Washington, D. C.

The first group, a Chicago team, departed from Minneapolis July 19 for three weeks of this service in Alaska. This team is composed of Drs. Jack Silverstein, Arthur Bernstein, George Holmes, Harry E. Barnett and John C. Fields, all from the Cook County Hospital in Chicago. The Alaskans will select their difficult cases in advance and assemble them in hospitals in order to avoid long trips and to save the time of the Chicago clinicians.

In accordance with Secretary Krug's request it is expected that another group of clinicians will be sent to Puerto Rico and the Virgin Islands in December for the purpose of aiding in difficult cases and of improving health conditions in those islands. The groups of clinicians selected will also work with public health officers, where they are available, in order to aid in bringing the best medical care to the underprivileged groups. Clinicians will be selected later from other medical centers to visit the Western Indian reservations. As this plan is expected to be continued, more clinical teams will be sent out next year.

Washington Letter

U. S. Mission to Combat Health Problems in Greece

Three U. S. Public Health service officers were assigned to the American Economic Aid Mission to Greece to help that nation combat tuberculosis, typhoid, dysentery, hookworm, infant mortality and other medical problems. After a first hand study they may request assistance of other American medical workers. A health service spokesman said the trio, whose names were not announced, would help direct expenditure of the $3,000,000 public health fund requested from Congress. The Greek death rate from tuberculosis is reported to be between 250 and 450 per hundred thousand of population as compared with 40 in the United States. Tremendous sanitation problems resulted from destruction of 23 per cent of all dwellings in Greece. It was also announced that Dr. R. R. Sayres, director of the Federal Bureau of Mines, has resigned to rejoin the U. S. Public Health Service staff.

House and Senate Conference Studies National Science Foundation Bills

A Senate-House conference is ironing out differences in bills passed by both sides of Congress for establishment of a twenty-four member National Science Foundation to promote fundamental research for health and national defense. The group would supervise scientific activities for the government and promote "pure science." The House approved its bill by voice vote last week, and recently the Senate approved a similar measure by a vote of 79 to 8. The legislation, backed by President Truman and leading scientists, would set up a program costing between $20,000,000 and $30,000,000 annually. The group could not engage in atomic energy research without approval of the Atomic Energy Commission. The House bill would direct the foundation to formulate national policy for promotion of fundamental research and education in sciences, support research related to national defense, grant scholarships and graduate fellowships in medical, biologic and other sciences, foster interchange of scientific information in the United States and foreign countries, and establish special commissions on cancer research, on heart and circulatory diseases and on poliomyelitis and other degenerative diseases. Foundation members would be appointed by the President subject to Senate approval.

Board Appointed to Select Students for Study Abroad

President Truman did not appoint a medical person to the ten man Board of Foreign Scholarships set up to select American students for study abroad under the Fulbright act. The State Department has received about 12,000 applications, of which 5,000 are from veterans having preference under law. The law authorizes agreements with foreign governments to use part of moneys paid for American war surplus materials to finance studies of Americans in foreign educational institutions and for travel of foreign students to study in this country. Russia is not now eligible but may qualify under lend-lease settlement. Countries eligible are Australia, Austria, Belgium, Czechoslovakia, Denmark, Egypt, Finland, France, Greece, Hungary, Iran, Italy, the Netherlands, the Netherlands East Indies, New Zealand, Poland, Siam, Turkey, the United Kingdom, Burma, the Philippines and China.

Pan American Congress of Pediatrics to Meet in Mexico City in 1949

The Pan American Congress for Pediatrics selected Mexico City for the second congress, to be held in 1949. More than 600 delegates and guests attended the closing sessions here. Dr. Felix Hurtado of Cuba was chairman. The chairman of arrangements was Dr. Edgar P. Copeland; Dr. Harry A. Ong, was assistant chairman.

Coming Medical Meetings

Alaska Territorial Medical Association, Fairbanks, July 28-30. Dr. William J. Blanton, Juneau, Secretary.

American Association of Obstetricians, Gynecologists and Abdominal Surgeons, Hot Springs, Va., The Homestead, Sept. 4-6. Dr. James R. Bloss, 418 Eleventh St., Huntington 1, W. Va., Secretary.

American College of Surgeons, New York, Waldorf Astoria Hotel, Sept. 8-12. Dr. Paul B. Magnuson, 40 E. Erie St., Chicago 11, Secretary.

American Congress of Physical Medicine, Minneapolis, Hotel Radisson, Sept. 2-6. Dr. Richard Kovacs, 2 E. 88th St., New York 28, Secretary.

American Congress on Obstetrics and Gynecology, St. Louis, Municipal Auditorium, Sept. 8-12. Mr. Karl S. Richardson, 24 West Ohio St., Chicago, Business Manager.

American Roentgen Ray Society, Atlantic City, Sept. 16-19. Dr. H. Dabney Kerr, University Hospitals, Iowa City, Secretary.

Colorado State Medical Society, Denver, Shirley Savoy Hotel, Sept. 17-20. Mr. Harvey T. Sethman, 1612 Tremont Place, Denver 2, Executive Secretary.

National Medical Association, Los Angeles, Aug. 18-22. Dr. John T. Givens, 1108 Church Street, Norfolk 10, Va., Secretary.

Nevada State Medical Association, Reno, Sept. 4-6. Dr. Moreton J. Thorpe, 17 N. Virginia St., Reno, Secretary.

Oregon State Medical Society, Portland, Sept. 4-6. Dr. Thomas S. Saunders, 1020 S. W. Taylor St., Portland 5, Secretary.

Pennsylvania, Medical Society of the State of, Pittsburgh, Hotel William Penn, Sept. 15-18. Dr. Walter F. Donaldson, 500 Penn Avenue, Pittsburgh 22, Secretary.

Southeastern Dermatological Association, Knoxville, Tenn., Hotel Andrew Johnson, Aug. 31. Dr. A. H. Lancaster, 608 W. Main Ave., Knoxville, Secretary.

Utah State Medical Association, Salt Lake City, Sept. 11-13. Dr. Ray T. Woolsey, 610 McIntyre Bldg., Salt Lake City 1, Secretary.

Western New York and Ontario Urological Society, Saranac, N. Y., Saranac Inn, Sept. 3-6. Dr. Albert M. Crance, 525 S. Main St., Geneva, N. Y., Secretary.

Bureau of Information

LOCATION OF PHYSICIANS

Virginia Shuler
Chicago

This is the sixth of a series of charts showing the trend in locations of physicians from April 1946 to January 1947.

"Conditions in Texas are still somewhat abnormal. During the past year we have been successful in a good many instances in locating doctors in certain communities. Nevertheless, we still have a rather extensive list of areas where doctors are needed. We are doing our best to get this information into the hands of doctors seeking locations, including Texas physicians, as well as physicians in other states. Efforts are being made by the Association, in cooperation with the three medical colleges in Texas, to impress all graduates with the need for physicians in rural areas and the advantages offered by such areas. There are no areas in the state at this time where the need for physicians is really critical. In most areas there is at least one physician within a radius of 25 miles. That has always been true in Western and Southwestern Texas, which is largely sparsely settled ranching country. Migration of physicians during the past year has shown a trend of movement from rural communities to the cities. The rural communities, however, could benefit greatly if money available under the Federal Hospital Construction Act were to be used in the construction of needed hospitals and health centers. Texas has 254 counties and 129 local medical societies. Every county in Texas is embraced in some medical society. At present there are forty or fifty small towns, communities and villages in Texas that have requested physicians. Not all of these requests represent real need, but most of them do. We keep in close touch with the proper officials and committees of county medical societies as to the need for doctors in their respective jurisdictions. We do not always list applications filed with us by drug stores, chambers of commerce, civic clubs, and so forth, or even doctors. We carefully check each claim and list only the deserving."

Dr. Holman Taylor, Secretary,
State Medical Association of Texas,
1404 West El Paso Street, Fort Worth 3.

Area in Arizona Requesting General Practitioner

County	Town	Population
Gila	Payson	487

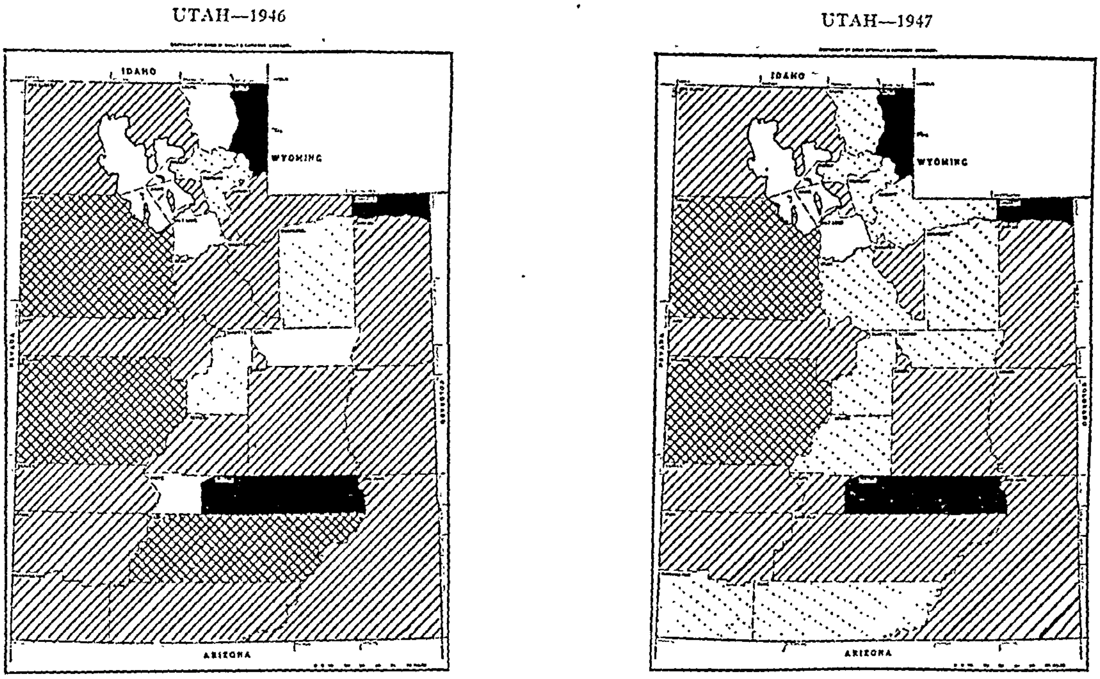
"Arizona is a state of great geographic distances, yet there are but fourteen counties in the vast expanse of the state. Each county maintains a county medical society, hence its populace is assured medical care. Several of the counties have heavy Indian populations and a scattered white population of lesser numbers. Two of the counties, Maricopa and Pima, account for better than two thirds of the white population of the state, Phoenix and Tucson (Maricopa and Pima counties respectively) being the two cities in which the population is centralized. Aside from these two cities there are few other towns equaling or topping 15,000 in population.

"All communities in the state supporting hospitals are presently well supplied with physicians and surgeons. The outlying districts needing and desiring more medical personnel will first need to set up hospitals and local facilities for the care of their sick.

"On the whole, Arizona has a full complement of doctors of medicine when facilities for caring for the sick of the state are fully considered. Specialists in practically every field of practice, and certified specialists, are fully represented in this complement of physicians and surgeons.

"As the white population in the more remote areas of the state increases and as hospital facilities become available in these areas, the spread of high class physicians and surgeons in such communities may be anticipated."

DR. FRANK J. MILLOY, Secretary,
The Arizona State Medical Association,
423 Heard Building, Phoenix.



Population, based on 1943 estimated Census figures, per active physician (excludes teaching, research, hospital administration, public health and state hospitals) by county.

"In general, I should say that the cities of 5,000 or more in population are well supplied with physicians at the present time, with the possible exception of a few specialists, such as nose and throat men, which are needed in certain areas In the rural areas there are still several localities which are entirely without any physician One could conservatively estimate that there are at least a dozen areas in the rural sections—towns of about 1,000 population—where good general practitioners are needed"

Dr H L January, Secretary,
New Mexico Medical Society,
Albuquerque

GOVERNMENT SERVICES

ARMY

ARMY AWARDS AND COMMENDATIONS

Colonel Derrick T. Vail

The Legion of Merit was recently awarded to Dr. Derrick T. Vail, now professor of ophthalmology at Northwestern University Medical School, Chicago. The presentation was made June 3 by Dr. Paul R. Hawley, medical director of the Veterans Administration, for outstanding services rendered in the European Theater of Operations from Oct. 5, 1942 to Oct. 14, 1944, when Colonel Vail served as senior consultant in ophthalmology at ETO headquarters. The citation read in part as follows: In addition to establishing and maintaining a singularly high standard for the treatment and supervision of ophthalmologic cases, Colonel Vail demonstrated exceptional qualities of adaptability and a thorough professional knowledge by encouraging the adoption of many improvements, resulting in the conservation of time and manpower. His whole hearted interest in the rehabilitation and care of blinded American soldiers, his keen foresight and exceptional devotion to duty reflect the highest credit on himself and on the armed forces of the United States. Dr. Vail graduated from Harvard Medical School, Boston, in 1923 and entered the military service in September 1942.

Colonel William D. Graham

The Legion of Merit has been awarded to Col. William Donald Graham, M. C., U. S. Army. The citation read in part as follows: For performing exceptionally meritorious services as commanding officer of the 158th General Hospital in England from November 1944 to July 1945. He was responsible for the outstanding accomplishments of the hospital in the field of neurosurgery and plastic surgery during a period of maximum flow of casualties. His work has reflected great credit on the Medical Department of the United States Army. Dr. Graham graduated from the University of Minnesota Medical School in 1930 and entered military service in 1934.

Colonel L. Holmes Ginn Jr.

The United States of America Typhus Commission Medal has been awarded to Col. L. Holmes Ginn Jr., M. C., U. S. Army. The citation read as follows: He performed meritorious service in connection with the work of the United States of America Typhus Commission during the period May 8 to July 10, 1945 in the Rhine Province Military District, Germany. As surgeon of the Fifteenth United States Army he exhibited keen foresight and rare judgment in planning and directing effective typhus fever control measures throughout the army area. Colonel Ginn has also been awarded the Legion of Merit and the Bronze Star Medal with the Oak Leaf Cluster. Colonel Ginn graduated from the Medical College of Virginia, Richmond, in 1927 and entered the military service in July 1927.

Major Arthur R. Hummel

The Legion of Merit was recently awarded to Major A. R. Hummel, M. C., A. U. S., now of Detroit, for exceptionally meritorious conduct in the performance of outstanding services in the Middle East from January 1943 to November 1945. Dr. Hummel graduated from Wayne University College of Medicine in Detroit in 1941 and entered the service June 12, 1942.

Dr. Herald R. Cox

The United States of America Typhus Commission Medal has been awarded to Dr. Herald R. Cox of Pearl River, N. Y. The citation read as follows: Dr. Herald R. Cox, civilian, distinguished himself as a consultant to the United States of America Typhus Commission from December 1942 to December 1945. While continuing his notable work with the development of typhus vaccine, he also gave valuable aid in producing serums to treat diseases of the typhus group and in investigating the problems of a vaccine against scrub typhus. His work was highly beneficial in the campaign against typhus fever and was a distinct contribution to scientific knowledge. Dr. Cox graduated from the School of Hygiene, Johns Hopkins University, in 1931.

NAVY

NAVY AWARDS AND COMMENDATIONS

Rear Admiral Charles S. Stephenson

The Legion of Merit has been awarded to Rear Admiral Charles S. Stephenson (MC), U.S.N., retired, of Washington, D. C. The citation read in part as follows: For exceptionally meritorious conduct in the performance of outstanding services as medical officer in charge of the division of preventive medicine in the Bureau of Medicine and Surgery and as navy medical representative on the National Research Council from Sept. 8, 1939 to Nov. 24, 1942. Displaying outstanding organizational ability and farsightedness in making recommendations concerning the preservation of health, he was in large measure responsible for safeguarding and maintaining the excellent physical condition of Navy, Marine Corps and Coast Guard personnel during World War II. He contributed to the success of the National Research Council in the execution of its vital war mission. His professional skill, initiative and tireless devotion to duty reflect the highest credit on himself and the United States Naval Service. Dr. Stephenson graduated from the Medical School of Vanderbilt University in 1912 and entered the naval service in 1913.

Captain Frederick R. Hook

The Navy Commendation Ribbon has been awarded to Capt. Frederick R. Hook (MC), U.S.N. The citation read as follows: For outstanding performance of duty as medical officer in command of the United States Naval Hospital at Oakland, Calif., from Sept. 1, 1942 to Nov. 15, 1943. By his outstanding professional and organizational skills he was in large measure responsible for completion of the expansion program which made his hospital the third largest naval hospital in the nation. Through his untiring efforts during this period he contributed to the efficient treatment rendered to thousands of war casualties and to the expeditious return to duty of a majority of these patients. Captain Hook's fulfilment of his exacting assignment was in keeping with the highest traditions of the United States Naval Service. Dr. Hook graduated from the University Medical College of Kansas City in 1913 and entered the military service in November 1917.

Captain James R. Thomas

The Navy Commendation Ribbon has been awarded to Capt. James R. Thomas (MC), U.S.N. The citation read in part as follows: For outstanding performance of duty as medical officer in command of the United States Naval Mobile Hospital Number One from May 2, 1942 to Oct. 31, 1943; and subsequently as medical officer in command of the United States Naval Hospital, Corpus Christi, Texas, from Nov. 10, 1943 to Aug. 1, 1945. By his constant devotion to the exacting details of his assignments, he contributed materially to the war effort and upheld the highest traditions of the U. S. Naval Service. Dr. Thomas graduated from the University of Illinois College of Medicine in 1917 and entered the naval service in September 1917.

Lieutenant Commander Charles R. Gennaria

The Navy Commendation Ribbon has been awarded to Lieut. Comdr. Charles R. Gennaria (MC), U.S.N.R., of Shamokin, Pa., for excellent service as senior medical officer aboard the U. S. S. *Leedstown* from Jan. 31 to Oct. 20, 1944, during the amphibious assaults and capture of Kwajalein, Guam, Peleliu and Leyte. During this period he organized and directed the activities of his department, which was taxed far beyond its normal capacity by the casualties from enemy action. That an exceptionally low death rate was achieved despite the fact that many of the seriously wounded were long delayed in reaching the ship is recognized in the citation as affording testimony to his outstanding ability and devotion to duty. His conduct and courage were at all times in keeping with the highest traditions of the United States Naval Service. Dr. Gennaria graduated from Jefferson Medical School in 1923 and entered the naval service Sept. 24, 1942.

PUBLIC HEALTH SERVICE

DR. SPENCER RESIGNS AS CHIEF

Dr. R. R. Spencer has resigned as chief of the National Cancer Institute of the U. S. Public Health Service, Washington, D. C., and Dr. Leonard A. Scheele, assistant chief of the institute, has been appointed chief. Dr. Spencer's resignation does not mean that he will withdraw from the work of the institute. He desired to be relieved of the increasing load of administrative duties in order to spend full time on "two phases of the cancer program that interest him most—professional education and research." In his new capacity he will direct the institute's expanding program for professional training of young physicians in the diagnosis and treatment of cancer and at the same time carry on research on the mechanism of cellular and species survival, which is related to the cancer process. Dr. Spencer is widely known also in the field of research for work in association with R. R. Parker in developing a vaccine against Rocky Mountain spotted fever.

Dr. Scheele has been in the Public Health Service since 1933 and was a member of the staff of the institute for several years before the war. During the war he served in Italy in Military Government and Allied Commission operations and later was in charge of the preventive medicine section of a division of supreme headquarters, Allied Expeditionary Force in Northwest Europe. He was also a representative of the medical section of the Allied Control Council in its initial operations in Berlin after Germany surrendered. He has been awarded the American Typhus Commission Medal and the Legion of Merit.

DR. IVY EXECUTIVE DIRECTOR OF ADVISORY COUNCIL

Dr. A. C. Ivy, Chicago, vice president of the University of Illinois, has been appointed executive director of the National Cancer Advisory Council to succeed Dr. George M. Smith, professor emeritus of Yale University, who resigned for reasons of health. Dr. Ivy, who was for many years head of the Department of Physiology at Northwestern University Medical School, has been a member of the council for two years. He will take up the part time post as executive director of the council on his return from Germany late in July.

VETERANS ADMINISTRATION

EDUCATIONAL COURSES FOR DISABLED VETERANS

About two hundred complete educational courses, ranging from high school subjects to automobile mechanics, are available to ill and disabled veterans in Veterans Administration hospitals. They are offered to patients as part of their educational therapy activities. The courses cover, in addition to academic high school material, a variety of prevocational and vocational technical subjects such as poultry raising, radio repair, photography and plastics. Commercial subjects include shorthand, typing, bookkeeping and problems of operating a small business. The two hundred courses available are listed in a catalogue distributed to all 126 Veterans Administration hospitals and homes.

One armed patients can learn to type in special classes organized by the Veterans Administration educational retraining sections. Despite their handicaps, these patients use standard typewriter keyboards in the course.

AWARD TO DR. HAWLEY

Dr. Paul R. Hawley, chief medical director of the Veterans Administration, has been awarded the Gorgas Award for 1947, which will be presented to him in Boston at the annual meeting of the Association of Military Surgeons, November 13-15. This award is given annually by the executive council of the Association of Military Surgeons for some notable contribution in the field of military medicine. It is sponsored by Wyeth, Incorporated, Philadelphia.

HOSPITAL IN MONTANA

The army engineers at Fort Peck, Montana, have opened the bids received for the construction of the 100 bed veterans' hospital at Miles City. The lowest bid was $4,437,000, which was 32 per cent above the government estimate of the cost of construction, and so no award has as yet been made.

PERSONALS

Brig. Gen. Guy B. Denit, who is on duty in the Surgeon General's Office, received the honorary degree of Doctor of Science from the Medical College of Virginia, Richmond, June 17.

Dr. Julian J. Keller has been assigned chief surgeon of the veterans' hospital at Tuscaloosa, Ala. Dr. Keller, who has been in the Veterans Administration service for many years and during World War II served in the medical corps of the Army, recently was on the staff of the veterans' hospital at Bay Pines, Fla.

Dr. Cyril H. Francis, Columbus, Ohio, has been appointed medical director for the Veterans Administration in Ohio, Michigan and Kentucky. Dr. Francis has been serving as chief of professional services with the Veterans Administration. He served in the navy medical corps during the war and previous to that time was in private practice in Los Angeles.

Dr. George T. McMahan has been assigned as manager of the Veterans Administration hospital at Gulfport, Miss., succeeding Dr. G. T. Sheffield, who has been assigned at his own request as psychiatrist to the Veterans Administration center at Biloxi.

Dr. Robert C. Cook, deputy director of the Veterans Administration department of medicine and surgery, represented the Veterans Administration at the International Congress of Military Medicine and Pharmacy in Switzerland, June 2-9. Dr. Cook is a graduate of Rush Medical College in Chicago and has been with the Veterans Administration since 1919.

Dr. Arthur Leiter has been appointed general medical examiner in Indiana by the Veterans Administration and will be located in Indianapolis. Dr. Leiter formerly practiced in Columbia City, Ind., and was health commissioner of Whitley County.

The plan to assign Dr. Cameron S. Guild to the branch office in San Francisco (THE JOURNAL, May 24, p. 384) was changed and he has been assigned to the branch office in New York City.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

COLORADO

School for Medical Record Librarians.—The University of Colorado, Boulder, will inaugurate September 1 an additional school for medical librarians which will lead to a Bachelor of Science degree from the school of business. Students will spend the first three years in the university proper and the fourth year of twelve months in the medical record library of Colorado General Hospital, Denver. The plans were drawn with the advice of the Educational Board of the American Association of Medical Record Librarians.

CONNECTICUT

Dr. Winternitz Acting Director of Research Fund.—The Jane Coffin Childs Memorial Fund for Medical Research has announced the appointment of Dr. Milton C. Winternitz, ew Haven, Conn., as acting director of the Board of Scientific dvisers to succeed Dr. Stanhope Bayne-Jones, who has accepted appointment as president of the joint administrative board of the New York Hospital-Cornell Medical Center (The Journal, June 7, p. 547). Dr. Bayne-Jones, director of the fund since its establishment June 11, 1937, will continue as a member of the Board of Scientific Advisers. The tenth anniversary of the fund was observed June 13 at a dinner in New Haven, Conn., attended by representatives of the U. S. Public Health Service, National Cancer Institute, Donner Foundation, Anna Fuller Fund, American Cancer Society, Committee on Growth of the National Research Council, Connecticut State Cancer Society and Yale University. The fund was established by gifts of $3,300,000 in trust to Yale University by the late Starling W. Childs and Miss Alice S. Coffin, New York. Dr. Bayne-Jones was the principal speaker. "The fund," he said, "has regarded the cancer problems as problems of growth and has supported work in fundamental fields of chemistry, biology, viruses, pathology, genetics and medicine." Of the eighty-one cancer projects it has supported, 78 per cent of those now in operation have been supported for three years or longer and some as long as ten years with provision up to twelve years. A fellowship program was put into operation in 1944 and twelve research fellowships have been granted. The fund is not restricted to any institution, although 40 to 60 per cent of its annual appropriations have been given to Yale. The present ratio is about evenly divided between cancer research at Yale and at other institutions in this country and abroad.

DISTRICT OF COLUMBIA

Medical Research at George Washington University.—George Washington University School of Medicine is operating this year the largest research program in its history under grants totaling $150,000. The largest grant, $40,000, is for research in anesthesia and the use of penicillin and streptomycin. Projects are under way for the study of drugs to treat typhus fever, Rocky Mountain spotted fever, rheumatic fever, tumors, arthritis and for relief of muscle spasms. Other projects deal with the study of hypertension, vitamins C and E, protein metabolism and therapy, cardiovascular disease and vascular surgery.

ILLINOIS

Federal Grant for Research in Psychology.—The University of Illinois, Urbana, has been given grants from the federal government totaling $87,850 for research and training in the field of psychology. The funds include $4,000 from the U. S. Public Health Service for fellowships and $7,250 for additional staff.

Fifty Years in Practice.—Dr. Robert W. Binney, Granite City, was given a dinner in honor of his completion of fifty years in the practice of medicine by the Tri-Cities Medical Society. Society members, classmates of Dr. Binney, representatives of industrial plants and the Chamber of Commerce of Granite City attended. The veteran doctor was presented a bronze plaque commemorating the occasion.

Chicago

Personal.—Dr. Fred L. Glenn was cited by the Kiwanis Club of Austin May 29 for unselfish service to various civic groups with which he has been actively associated.——Dr. William D. McNally, coroner's toxicologist for twenty-one years, resigned June 27.

Cook County Interns to Be Country Doctors.—A class of 58, including 4 women, began a two year internship at Cook County Hospital July 1 designed to train them as general practitioners. Dr. Karl A. Meyer, medical superintendent of the hospital, said that 99 per cent of the class when asked where they intended to practice said they would go into small communities where the need is greatest. This is the first class to enter the hospital under the new required two year internship regulation (The Journal, March 15, p. 791).

Research in Nucleonics.—Construction at the southwest corner of Ellis Avenue and 56th Street of a $1,250,000 ion accelerator building, first unit in the University of Chicago's $10,000,000 program for basic research in nucleonics, began July 9. This laboratory will house a 100 million volt betatron and two cyclotrons of the most modern construction. The first building in the proposed housing program for the Institute for Nuclear Studies, the Institute of Radiobiology and Biophysics and the Institute for the Study of Metals will be a one story structure with basement. The facilities for medical research will be used by the Institute of Radiobiology and Biophysics and the division of roentgenology of the department of medicine. One problem in prospect is a study of the effects of positive ion beams on deep-seated cancer. The accelerator building, to be ready for occupancy next spring, will make possible the resumption of advanced basic research, which has been at a standstill since the war. Among the many scientists at the university who will work in the laboratory are Samuel K. Allison, who participated in the first atomic bomb explosion in New Mexico; Enrico Fermi, Nobel prize winner, who was the first to achieve a controlled nuclear chain reaction; Harold C. Urey, discoverer of "heavy water" and Nobel prize winner; Arthur J. Dempster, discoverer of U-235; Edward Teller and Willard F. Libby, who with associates, according to the university's press release, "lately discovered radiocarbon in all living matter"; Raymond E. Zirkle, Dr. Austin M. Brues, Kenneth S. Cole and Konrad E. Bloch. Dr. Paul C. Hodges, roentgenologist, will have charge of the medical aspects of the program. The ion accelerator building will be of fireproof construction. The large cyclotron will be placed in the pit, so that its beam will be underground and not detectable by the betatron, which, together with the present cyclotron, will be enclosed in concrete walls. Five laboratories, offices for the medical staff and examining rooms for patients will be located the full length of the building. Offices, laboratories, conference room and drafting room for the Institute for Nuclear Studies and an office and laboratory for the Institute of Radiobiology and Biophysics will be located on the east balcony.

INDIANA

Appoint Assistant to Dean.—John J. Mahoney, Ph.D., formerly on the University of Illinois faculty, has been appointed assistant to the dean and assistant professor of experimental medicine at the Indiana University Medical Center, Indianapolis. Dr. Mahoney received his Ph.D. degree from the State University of Iowa, Iowa City. He has been an instructor in zoology and research associate in zoology at the State University of Iowa, Iowa City.

KANSAS

Changes in Health Officers.—The state board of health has announced the following changes in health officers: Dr. Samuel B. Muller, Pittsburg, has been appointed city health officer to replace Dr. Otto B. Kiehl. Dr. John M. Porter, Concordia, resigned as health officer of Cloud County after his appointment as a member of the Kansas State Board of Health; Dr. Frank Kinnamon, Concordia, will succeed him. Dr. Robert M. Heilman, Topeka, formerly director of the industrial hygiene division of the state health department, has returned to the Kansas State Board of Health as director of the newly created division of hospital survey and construction.

KENTUCKY

Division of Psychosomatic Medicine.—Grants totaling $49,304 for three departments of the University of Louisville School of Medicine have been received from the U. S. Public Health Service to provide funds for research and expansion of present facilities. A division of psychosomatic medicine in the school is to be organized, and two fellowships of $3,600 in that field will be offered. The grant will make possible the addition of one associate professor with special training, one society worker, one psychologist and two part time specialists. The department of anatomy received $9,960 for a study of toxemia of pregnancy in guinea pigs. In the department of pharmacology a $7,344 grant will be used to study the peptic ulcer problem.

MAINE

State Medical Election.—At the annual meeting of the Maine Medical Association at York Harbor, June 22-24, Dr. Stephen A. Cobb, Sanford, was elected president; Dr. Forrest B. Ames, Bangor, president-elect, and Dr Frederick R. Carter, Portland, secretary-treasurer.

Maine Psychiatric Society.—This society was founded at the Augusta State Hospital, June 19, for group consideration of all matters relating to psychiatry in the state. Officers elected were Dr. Carl J. Hedin, Bangor, medical superintendent, Bangor State Hospital, president; Dr. Frederick R. Carter, Portland, vice president; Dr. Francis H. Sleeper, medical director of the Augusta State Hospital, Augusta, secretary-treasurer.

MARYLAND

Gift to Johns Hopkins University.—Johns Hopkins University, Baltimore, announced on July 11 a gift of $1,000,000 from Undersecretary of State and Mrs. Will L. Clayton for medical research. The terms of the gift permit it to be used for any research regarded as most important to the department of medicine "in the present state of development of the medical sciences."

Adolf Meyer Laboratory of Neurology.—The medical advisory board of the Seton Institute and the Sisters of Charity of St. Vincent de Paul, Baltimore, have announced the gift from Dr. Adolf Meyer, Baltimore, of his entire personal collection of neuroanatomic and neuropathologic material, consisting of some sixty large boxes of serial sections from crucial human case material as well as material of a comparative nature. Included in the gift is an exhaustive card index file of neurologic subjects. The institute plans to use this material as the nucleus about which to develop a laboratory, which will be called the Adolf Meyer Laboratory of Neurology, for the study of neuroanatomy, neurophysiology and neuropathology. The material will soon be in available form for the instruction of candidates for the American board examinations in neurology. Seton Institute, the former Mount Hope Retreat, provides facilities for the training of psychiatric interns and for three years of postgraduate service required of the specialists certified by the American Board of Psychiatry and Neurology. Dr. Wendell S. Muncie, Baltimore, is chairman of the medical advisory board.

MASSACHUSETTS

Personal.—Dr. Frank H. Lahey, founder and director of the Lahey Clinic, Boston, received the honorary degree of Doctor of Science June 18 from Northwestern University, Evanston, Ill.

Lectures in Public Health.—"What's New in Public Health," a series of twelve lectures for public health workers in the North Metropolitan District of the Massachusetts Department of Public Health, has just been completed. Dr. A. Daniel Rubenstein, health officer of the district, planned the lectures to bring professional workers up to date in this field. The expenses of the course were assumed by the Middlesex Health Association, and the Harvard School of Public Health offered its facilities. Members of the Harvard School of Public Health faculty, the staff of the Massachusetts Department of Public Health and national public health experts gave the lectures to sixty-seven public health workers including board of health, school and industrial nurses, board of health agents and health educators.

Dr. Eaton Appointed Associate Professor.—Dr. Monroe D. Eaton, director of research laboratory of the state department of public health at the University of California, Berkeley, was appointed associate professor of bacteriology and immunology in Harvard Medical School, effective July 1. A graduate of Harvard Medical School, Boston, 1930, he served for three years as assistant in bacteriology and immunology in that school. From 1933 to 1936 he was an instructor in bacteriology at the Yale University School of Medicine, New Haven, Conn., and the following year was assistant professor of bacteriology and immunology in Washington University School of Medicine, St. Louis. Since 1937 he has been a member of the staff of the International Health Division of the Rockefeller Foundation and director of the research laboratory for the state of California.

MICHIGAN

Dr. Stapleton Retires.—Dr. William J. Stapleton Jr., Detroit, actively connected with teaching at the Detroit College of Medicine from 1907 and since 1914 professor of medical jurisprudence, as well as assistant, associate or acting dean since 1935, has retired. In addition to his teaching he has been engaged in active practice of medicine for forty-seven years. He received his M.D. from Michigan College of Medicine and Surgery, Detroit, in 1900, his Ph.G. from the department of pharmacy in the Detroit College of Medicine, 1902, and his LL.B. from Detroit College of Law, 1907.

Whooping Cough in Michigan.—According to Dr. William DeKleine, commissioner, Michigan Department of Health, Lansing, whooping cough, which is now appearing in the state at the rate of 200 cases a week, has taken the lives of 33 children during the first five months of this year. Eighteen of these deaths were of babies under 6 months of age. A total of 5,312 cases have been reported in the state since January 1. The Michigan Department of Health recommends that all babies at 6 months of age be given four weekly doses of vaccine, which is made by the Michigan Department of Health laboratories and distributed without charge to physicians in the state.

Course in Food Handling.—The School of Public Health, University of Michigan, gave a course on food handling from June 19 to 21 designed to serve the needs of public health workers confronted with problems of food handler education and food establishment sanitation The course was planned with the assistance of various industries such as drug stores, restaurants and hotels, and the university, the U. S. Public Health Service, Illinois state health department and the National Sanitation Foundation, the chairman of the group being Henry F. Vaughan, Dr.P.H., dean of the School of Public Health, University of Michigan. The course was attended by health workers from various parts of the United States, and three day discussions were presided over by Dr. Vaughan, Dr. Herman N. Bundesen, Chicago Board of Health, and Jerome Trichter, director of the Bureau of Food and Drugs, New York.

Rheumatic Fever Program.—Rheumatic fever, which kills five times as many children as infantile paralysis and cripples many more, is being attacked on a statewide basis in Michigan under a program set up by the committee from the state medical association. Joint sponsors of the program are the Michigan State Medical Society, Michigan Crippled Children Commission and the Michigan Society for Crippled Children and Disabled Adults, Inc. The objectives are (1) recognition and proper management of every case in Michigan, (2) determination of the incidence of the disease, (3) provision for special hospital and convalescent care centers, (4) education and continuous recourse to recent advances in research and (5) lay education and lay group cooperation. Nine rheumatic fever consultants and diagnostic centers have been established in the state and additional centers are to be set up in Muskegon, Wayne County, Battle Creek, Saginaw and Port Huron. Where the families cannot afford it, the small laboratory cost fee is paid through the Michigan Crippled Children's Commission. New cases are reported to the state health department, and monthly reports are submitted to the central office of the Michigan State Medical Society by the centers. Physicians return cases to the centers at intervals for reappraisal.

MINNESOTA

Research Professor in Rheumatic Fever.—Plans have been formulated to establish at the University of Minnesota, Minneapolis, a professorship which will direct research in heart diseases and rheumatic fever of children. The American Legion of the state of Minnesota is embarking on a campaign to secure $500,000 from its members to maintain this chair as a memorial to veterans of World Wars I and II.

Townspeople Fete Dr. Grinnell.—Hundreds of townspeople as well as patients throughout the surrounding country attended a homecoming in Preston, Minn., recently in honor of Dr. Wendell B. Grinnell, who has practiced medicine for forty-seven years. Dr. Grinnell began practicing in Fillmore County in 1900 and one year later moved to Preston. For many years he owned and operated his own hospital.

MONTANA

New Cancer Service.—The Cancer Committee of the Montana State Medical Association is inaugurating a program to provide medical service and hospital expenses for medically indigent cancer patients, interest free loans for people temporarily unable to pay, tissue examinations and outpatient care. The project has been worked out in cooperation with the state board of health and the department of public welfare, which has volunteered to do the case work. Dr. Eugene Hildebrand, Great Falls, is chairman of the state division's executive committee, which will supervise the operation of the project.

NEW YORK

Dr. Hilleboe Appointed State Health Commissioner.—Governor Dewey appointed Dr. Herman E. Hilleboe, Assistant Surgeon General of the U. S. Public Health Service, to take over the duties of the New York State Health Commissioner on July 1, succeeding Dr. Edward S. Godfrey, who has retired (THE JOURNAL, May 31, p. 472). Dr. Hilleboe graduated from the University of Minnesota Medical School in 1931 and received a Master of Public Health degree in 1935 at Johns Hopkins School of Hygiene and Public Health, Baltimore. For a time he engaged in general practice in Swanville, Minn., and since 1935 has spent full time in public health work specializing in tuberculosis control. In 1939 he was appointed senior surgeon in the regular corps of the Public Health Service. From 1939 to 1942 he was chief of the medical unit, Minnesota Division of Social Welfare, in St. Paul, on loan from the Public Health Service, and has since been in tuberculosis control work in the Public Health Service, Washington, D. C. He has been Assistant Surgeon General since Nov. 1, 1946. Dr. Hilleboe is a member of the board of directors of the National Tuberculosis Association, a member of the Council of the American Trudeau Society and of the Board of Regents of the American College of Chest Physicians and representative on the Council of the International Union Against Tuberculosis. He is professorial lecturer in tuberculosis at the George Washington University Medical School, Washington, D. C., and adjunct professor of medicine, Georgetown University, Washington. He is the American member of the Expert Committee on Tuberculosis of the World Health Organization Interim Commission.

New York City

Cancer Professorship.—Cornell University Medical College has established a professorship of cancer with an annual endowment of $15,000 for five years. The sum represents the first allocation of funds from the 1947 campaign of the New York City Committee of the American Cancer Society.

Venereal Disease Seminar for Practicing Physicians.—A new series of lectures for practicing physicians on the diagnosis, treatment and management of venereal diseases will start at the New York City Department of Health, 125 Worth Street, Manhattan, on Saturday morning, September 13. Meetings will be held every Saturday morning at 10:30 through December 20. Experts in special fields of venereal disease control will participate in the seminar. No registration or fee for the course will be required. Physicians who attend may be reached by their offices at WOrth 2-6900, extension 460.

Rehabilitation Wards Opened.—Mayor William O'Dwyer formally opened two new wards at New York's municipal Bellevue Hospital July 7, designed to provide a complete program of rehabilitation for disabled civilians similar to that available to disabled veterans through the Veterans Administration. The two wards, which will accommodate 80 patients, are claimed to comprise the first rehabilitation program in any civilian general hospital in the nation. The new program is an outgrowth of a grant of $250,000 in 1944 by the Baruch Committee on Physical Medicine to the New York University College of Medicine, which is responsible for the professional services of the new department. Dr. Howard A. Rusk, head of the department of rehabilitation and physical medicine, New York University College of Medicine, was appointed consultant in rehabilitation to the department of hospitals of the city health department. He will supervise the expansion of the program into other city hospitals. It is expected that the 80 rehabilitation beds in Bellevue will eventually be expanded to about 600 when the new Bellevue Hospital is constructed.

NORTH CAROLINA

University Promotions.—Duke University School of Medicine, Durham, has announced the promotion of Dr. Lenox D. Baker to professor of orthopedics; Dr. Jasper L. Callaway to professor of dermatology and syphilology; Dr. Robert W. Graves to professor of neurology; Dr. M. Barnes Woodhall to professor of neurosurgery; Philip Handler, Ph.D., to associate professor of biochemistry, and Dr. Jerome S. Harris to associate professor of pediatrics.

Appoint College Physician.—Dr. Cary F. Irons, Greenville, has been appointed physician at East Carolina Teachers College, Greenville, effective September 1, replacing Dr. Fredcrick P. Brooks, who has held the position since 1935. Dr. Irons received his M.D. degree at the Medical College of Virginia, Richmond. During World War II he served in the medical reserve corps and was discharged as a major. Dr. Brooks will devote full time to private practice.

SOUTH CAROLINA

Health Officer Assigned.—Dr. Carolyn H. Callison, formerly health officer for Greenwood and McCormick counties, has returned to the state board of health after receiving her Master of Public Health degree from Columbia University College of Physicians and Surgeons, New York, and has been assigned to the Charleston County Health Department. She also served four years as a county health officer in Alabama.

TEXAS

Appointed to State Board.—The appointment of the following doctors to the state board of medical examiners has been announced: Drs. McKinley H. Crabb, Forth Worth; Herschel F. Connally, Waco, and Neil D. Buie, Marlin, were reappointed. Dr. Ralph H. Peterson, Wichita Falls, will serve his first term.

New Surgical Unit.—A special surgical unit for plastic and maxillofacial surgery and neurosurgery is being developed at the University of Texas Medical Branch, Galveston, to be opened in September. This unit was planned by the late Dr. Albert O. Singleton and includes an operating suite with x-ray appliances, offices, wards and private rooms. The new unit will be under the direction of Dr. Truman G. Blocker Jr., professor of plastic and maxillofacial surgery, and Dr. Samuel R. Snodgrass, associate professor of neurosurgery.

Drs. Blattner and Brown to Head Departments.—Baylor University College of Medicine, Dallas, has announced the appointment of Dr. Russell J. Blattner, associate professor of pediatrics, Washington University School of Medicine, St. Louis, as professor and chairman of the department of pediatrics, beginning September 1. Dr. Blattner received his M.D. degree from Washington University School of Medicine, St. Louis, in 1933. He was an intern in 1934, an assistant resident in 1935 and a resident, all at St. Louis Children's Hospital. Dr. Warren T. Brown, formerly associate professor of psychiatry at Yale University School of Medicine, New Haven, on July 1 was made professor of psychiatry and chairman of the department of neuropsychiatry at Baylor University. He received his medical degree from the University of Texas Medical Branch, Galveston, in 1933 and went to Yale University School of Medicine as assistant professor of psychology and mental hygiene.

UTAH

University Appointments.—The University of Utah School of Medicine, Salt Lake City, has announced the following additions to its medical staff: Thomas F. Dougherty, Ph.D., has been appointed professor in the department of anatomy (histology). Dr. William Moretz, recently instructor in surgery at Rochester University, Rochester, N. Y., has joined the staff as assistant professor in the department of surgery, succeeding Dr. Randolph T. Shields, who has left for China. Dr. Hans Reich of the University of Basel, Basel, Switzerland, will join the staff to assist in a cancer research project now under way in the department of biochemistry, financed by grants from the Cancer Research Division of the Donner Foundation and the U. S. Public Health Service.

WASHINGTON

Reinstate Course for Medical Speakers.—King County Medical Speakers Club will present a special course consisting of ten consecutive Monday night sessions beginning September 15 and a similar series beginning Wednesday, September 17. The special course will feature speech fundamentals, how to write a speech, manuscript reading, radio technic and parliamentary law. The course, under Mr. Clayton L. Walton, state parliamentarian for the Junior Chamber of Commerce, was presented in 1941 and 1942 also. Further information may be obtained by writing the King County Medical Society, 118 Cobb Building, Seattle 1.

GENERAL

Special Society Elections.—At the annual meeting of the American Association on Mental Deficiency in St. Paul, May 27-31, Lloyd Yepson, Ph.D., Trenton, N. J., was elected president; Dr. Edward J. Humphreys, Columbus, Ohio, president-elect and editor of the journal; Dr. Neil A. Dayton, Mansfield Depot, Conn., secretary-treasurer. Final plans are outlined for the first International Congress on Mental Deficiency, which will be held in Boston at the Hotel Statler May 11-15, 1948.——At the annual meeting of the American College of Radiology in

Atlantic City June 8 Drs. Edwin C. Ernst, St. Louis, was elected president, Charles L. Martin, Dallas, Texas, vice president, Warren W. Furey, Chicago, treasurer and Mac F. Cahal, Chicago, executive secretary.

Gastroscopic Club Changes Name.—At the recent meeting of the American Gastroscopic Club in Atlantic City the name of the organization was changed to the American Gastroscopic Society. The group elected Drs. Herman J. Moersch, Rochester, Minn., president; James L. Borland, Jacksonville, Fla., vice president, and Joseph B. Kirsner, Chicago, secretary-treasurer.

Research in Multiple Sclerosis.—Contribution of $25,000, made by Mrs. Percy S. Straus, New York, has been announced by the Association for Advancement of Research on Multiple Sclerosis, Inc. With this contribution the initial goal of $100,000 for research on multiple sclerosis has been met. The first grant made by the association was for $64,350 for work in the field of allergy (The Journal, June 21, p. 722).

National League of Nursing Education.—The National League of Nursing Education will hold its fifty-first convention in Seattle September 8-11. The theme of the convention will be "Nursing Education for Public Service." The Hawaii League of Nursing Education will be formally accepted into the National League at this time. Details may be obtained from the National League of Nursing Education, 1790 Broadway, New York 19.

Dr. Kato Awarded Prize for Painting.—Dr. Hideo H. Kato, intern at the General Hospital, Louisville, Ky., won the $250 prize of the American Physicians Art Association at the exhibit held in Atlantic City in June. The painting dedicated to "combat medics" is entitled "Beyond the Call of Duty." Dr. Kato, a young Japanese American, graduate of the University of Louisville School of Medicine in 1941, served in the U. S. Army overseas twenty months. He had no previous training in art and began painting as a hobby after the war.

Publicity Campaign Against Tuberculosis.—The National Tuberculosis Association reports that the Advertising Council, Inc., will launch a nationwide publicity campaign urging periodic chest x-rays for all adults. The campaign, approved by the National Tuberculosis Association in March, will use newspapers, magazines, radio and display to drive home the necessity of early diagnosis. Space and time will be donated through the council by sponsors and advertisers who are represented in the council and whose contributions mainly support it.

The Banting Lecture.—Dr. George H. A. Clowes, Ph.D., director emeritus of the Lilly Research Laboratories, delivered the annual Banting memorial address of the American Diabetes Association at its recent meeting in Atlantic City and was awarded the Banting Medal, given in recognition of distinguished service in the field of diabetes. Under Dr. Clowe's direction the laboratories cooperated with the University of Toronto Faculty of Medicine, Ontario, and Drs. Banting and Best in the early development of insulin of sufficient purity and stability to permit its widespread clinical use throughout the world.

Scientific Attack on Problem Drinking.—The first large scale nationwide attack on problem drinking will be launched this fall by the Research Council on Problems of Alcohol. Organized ten years ago, the Research Council has been sponsoring individual research projects among scientific institutions to get at the fundamental causes of problem drinking, which affects the lives of over 750,000 persons in the United States. The primary objectives of the council are not only to learn more about these fundamental causes but to develop effective methods of treatment and prevention. It hopes to establish research diagnostic and treatment centers in leading medical schools and their affiliated hospitals. One has already been established at Cornell University Medical College–New York Hospital under a grant of $150,000 covering a five year period.

Radio Program on Rural Medical Service.—The Allis-Chalmers Manufacturing Company, West Allis, Wis., sponsors of the National Farm and Home Hour broadcast each Saturday noon over the radio facilities of the National Broadcasting Company and its independent affiliated stations, will deal with the problem of rural medical service in a special broadcast scheduled for August 2 at 12 noon, Central Standard time. Special guests on this program, representing the rural physician and his wife, will be Dr. and Mrs. Charles C. Collester of Spencer, Iowa. Arrangements for Dr. and Mrs. Collester to appear on the program were made by the Bureau of Health Education of the American Medical Association through the Iowa State Medical Society. Dr. and Mrs. Collester will travel to Chicago to broadcast from WMAQ as the special guests of the sponsors.

International Cancer Research Congress.—The fourth International Cancer Research Congress will be held in St. Louis, September 2-7, with headquarters at the Jefferson Hotel, under the sponsorship of the Union Internationale Contre le Cancer and the American Association for Cancer Research. General sessions will include presentations on the following topics:

September 3. General Aspects of Cancer Research; Cancer Surgery; Radiation Therapy of Cancer; Etiology of Cancer.
September 4. Etiology of Cancer (Carcinogens); Chemistry in Relation to Cancer.
September 5. Hormones and Cancer; Biology of Cancer.
September 6-7. Nuclear Physics in Relation to Cancer; Cancer and the Host.

Edmund V. Cowdry, Ph.D., Barnard Free Skin and Cancer Hospital, St. Louis, is president of the Congress, Dr. Shields Warren, New England Deaconess Hospital, Boston, is chairman of the Program Committee, and Dr. Axel N. Arneson, Mellinckrodt Institute of Radiology, St. Louis, is chairman of the Committee on Local Arrangements.

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the periods indicated have been received from the division of public health methods, U. S. Public Health Service:

	Week Ended			Total to		Total *

Deaths

Linda Bartels Lange, Philadelphia; Johns Hopkins University School of Medicine, Baltimore, 1911; professor of bacteriology and immunology at the Woman's Medical College of Pennsylvania from 1937 to 1940; fellow in pathology and bacteriology at the Rockefeller Institute for Medical Research, New York, from 1912 to 1914 and pathologist and director of the laboratory at the Howard A. Kelly Hospital, Baltimore, 1914-1915; instructor in pathology at the University of Wisconsin Medical School in Madison, 1915-1916, and instructor and assistant in medicine at the Johns Hopkins University School of Medicine in Baltimore from 1916 to 1919; fellow, instructor and associate in bacteriology at the Johns Hopkins University School of Hygiene and Public Health in Baltimore from 1919 to 1927, when she became associate professor, serving until 1937; died April 24, aged 65, of pneumonia.

Delbert Oscar Kearby, Indianapolis; born in Rivervale, Ind., Dec. 31, 1878; Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1906; formerly professor of bronchoscopy and esophagoscopy at the Indiana University School of Medicine, where he had been in charge of the department; at one time served in the house of representatives of the state of Washington; specialist certified by the American Board of Otolaryngology; fellow of the American College of Surgeons; past president of the Indiana Academy of Ophthalmology and Otolaryngology; served on the staffs of the Indianapolis City Hospital, Robert W. Long Hospital, St. Vincent's Hospital, James Whitcomb Riley Hospital for Children and the Methodist Hospital, where he died April 10, aged 68, of rupture of the abdominal aorta.

George Edward Perkins, Boston; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1913; member of the American Medical Association; served during World War I; during World War II served as a lieutenant colonel in the medical corps, Army of the United States, directing the venereal disease control program of the Sixth Army Corps and a consultant with rating boards under the Veterans Administration; acting director, division of venereal diseases, Massachusetts Department of Public Health; consultant at the Boston Dispensary and Massachusetts Memorial Hospitals; died in the Burbank Hospital, Fitchburg, April 3, aged 68, of injuries received in an automobile accident.

Joseph Johns ⊕ Ionia, Mich.; born on May 10, 1882; American Medical Missionary College, Battle Creek, Mich., and Chicago, 1910; past president of the Ionia-Montcalm Counties Medical Society; an examiner for the draft board of Ionia County during World War II; on the staffs of the Michigan Reformatory and the Ionia State Hospital; member and past president of the staff of the Ionia County Memorial Hospital; member of the staff of the Clinton Memorial Hospital, St. Johns; visiting surgeon to St. Mary's Hospital and the Blodgett Memorial Hospital in Grand Rapids, where he died April 6, aged 64, of cerebral hemorrhage.

John Daniel Donovan, Detroit; St. Louis University School of Medicine, 1935; interned at the Providence Hospital; member of the American Medical Association, American Association of Industrial Physicians and Surgeons and the Michigan Association of Industrial Physicians and Surgeons; industrial physician for the Ford Motor Company, serving as a member of the Rouge plant industrial hospital staff and during World War II assistant physician in charge of the industrial hospital at the Willow Run bomber plant; died in the Henry Ford Hospital April 18, aged 35, of uremia secondary to sulfadiazine anuria.

John T. Harrington, Waco, Texas; Louisville (Ky.) Medical College, 1887; for many years chairman of the board of trustees and official physician at the Baylor University, where in 1945 the dormitory was named for him; served as president of the board of health of El Paso, as city physician of Waco, as supervisor of Texas penitentiaries and as director of the Epileptic Colony in Abilene; one of the founders of the Hardin-Simmons University at Abilene; on the staffs of the Providence and Hillcrest Memorial hospitals; died April 29, aged 89, of carcinoma of the prostate.

Horace Woodward Carle ⊕ St. Joseph, Mo.; Bennett Medical College, Chicago, 1914; past president of the Buchanan County Medical Society; past president and for many years a member of the school board; member of the American Heart Association and the Southern Medical Society; fellow of the American College of Physicians; formerly member and for one year president of the state board of health; affiliated with the Missouri Methodist Hospital and St. Joseph's Hospital; died April 27, aged 57, of pulmonary embolism, chronic heart disease and pneumonia.

Joseph Vincent S. Dauksys, Beacon, N. Y.; Rush Medical College, Chicago, 1926; member of the American Medical Association, Radiological Society of North America and the American College of Radiology; at one time secretary-treasurer of the Mercer County (Ill.) Medical Society; for many years affiliated with Veterans Administration hospitals at various places; major in the medical corps, Army of the United States, during World War II assigned to the Veterans Administration Hospital in Castle Point; died April 6, aged 47, of pulmonary tuberculosis.

William Dietrich Aufderheide ⊕ St. Louis; Marion-Sims College of Medicine, St. Louis, 1898; also a graduate in pharmacy; on the staffs of the Alexian Brothers Hospital, Deaconess Hospital and the Lutheran Hospital, where he died April 16, aged 71, of cerebral hemorrhage and hypertension.

Joseph E. Benton, Central City, Neb.; Omaha Medical College, 1897; member of the American Medical Association; on the staffs of St. Francis Hospital in Grand Island and the Hord Memorial Hospital; surgeon for the Union Pacific and Burlington railroads; died in St. Joseph's Hospital in Omaha April 22, aged 71, of carcinoma of the cecum with metastases to the liver.

Thomas Franklin Beveridge ⊕ Muscatine, Iowa; Kentucky School of Medicine, Louisville, 1891; affiliated with the Benjamin Hershey Memorial Hospital, where he died April 22, aged 80, of coronary occlusion.

Charles David Bles, New York; Fordham University School of Medicine, New York, 1911; served as medical officer with the 102d Engineers of the New York National Guard, on the Mexican border and during World War I; died in Veterans Administration Hospital number 81, March 5, aged 68.

John A. Boyd ⊕ Santa Barbara, Calif.; Western Pennsylvania Medical College, Pittsburgh, 1903; died April 9, aged 69, of coronary occlusion.

John Francis Boyle ⊕ Lowell, Mass.; Harvard Medical School, Boston, 1903; member of the New England Obstetrical and Gynecological Society; past president of the Middlesex North Medical Association; on the staff of St. Joseph's Hospital; died April 25, aged 75, of arteriosclerotic heart disease.

Thomas L. Bradley, Warrensburg, Mo.; Washington University School of Medicine, St. Louis, 1896; county jail physician; served as county coroner; died April 10, aged 76, of arteriosclerosis.

Frank Erwin Brinckerhoff ⊕ Beloit, Wis.; University of Illinois College of Medicine, Chicago, 1913; fellow of the American College of Surgeons; served during World War I; on the staff of the Beloit Municipal Hospital; died in St. Petersburg, Fla., April 19, aged 56, of coronary occlusion.

Frank Elbert Burbank ⊕ Oxford, Iowa; State University of Iowa College of Medicine, Iowa City, 1892; died in the Community Hospital, Pleasantville, April 19, aged 90, of cerebral hemorrhage.

Sidney Raymond Carsley ⊕ Palmer, Mass.; University of Vermont College of Medicine, Burlington, 1902; medical examiner for Hampden District; affiliated with the Wing Memorial Hospital in Palmer, Mary Lane Hospital in Ware and the Springfield Hospital in Springfield, where he died April 19, aged 71, of coronary thrombosis.

Levi Bennett Cochran ⊕ Hartford, Conn.; University of Pennsylvania Department of Medicine, Philadelphia, 1893; served on the staff of the Hartford Hospital, where he died April 21, aged 79, of coronary sclerosis with infarction.

Morris Coplan ⊕ Cleveland; University of Wooster Medical Department, Cleveland, 1897; member of the Cleveland Academy of Medicine; served on the staff of the Mount Sinai Hospital; on the staffs of the Lutheran Hospital and the Fairview Park Hospital, where he died April 3, aged 73, of coronary thrombosis.

Herbert Richard Crase, Los Angeles; Stanford University School of Medicine, San Francisco, 1927; member of the American Medical Association; on the staffs of the California Lutheran Hospital and the Queen of Angels Hospital, where he died February 21, aged 45, of hypertension and uremia.

Ira Alexander Dailey, Micanopy, Fla.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1916; member of the American Medical Association; affiliated with the Alachua County Hospital; died in Gainesville April 14, aged 56, of carcinoma of the bladder.

Lawrence Leroy Davidson ⊕ Santa Monica, Calif.; University of Nebraska College of Medicine, Omaha, 1926; on the staffs of the Santa Monica and St. John's hospitals; died in Los Angeles April 21, aged 45, of arteriosclerosis and coronary occlusion.

Samuel H. Dillard, Brookhaven, Ga.; Atlanta Medical College, 1883; died March 16, aged 86, of uremia.

William James Donahue ⊕ Newark, N. J.; Long Island College Hospital, Brooklyn, 1909; member of the American Psychiatric Association; served during World War I; received a certificate of appreciation from the War Department for service on the Induction Examining Board in the New Jersey-Delaware Recruiting and Induction District during World War II; on the staffs of the City Hospital, St. Michael's Hospital and Presbyterian Hospital, where he died April 18, aged 63, of carcinoma of the left lung.

Robert P. Donaldson, Pontotoc, Miss.; Memphis (Tenn.) Hospital Medical College, 1901; member of the American Medical Association; for many years county health officer; member of the Selective Service Board during World War II; for many years vice president of the Bank of Pontotoc; died in the Community Hospital, Tupelo, April 30, aged 70, of injuries received in an automobile accident.

Roswell Thomas Eldon, Altoona, Pa.; Jefferson Medical College of Philadelphia, 1891; member of the American Medical Association; served on the staffs of the Mercy and Altoona hospitals; died April 12, aged 79, of coronary thrombosis.

Ord Everman, Indianapolis; Indiana University School of Medicine, Indianapolis, 1908; served during World War I; psychiatrist for the Veterans Bureau and had been stationed at hospitals in various parts of the country; died April 21, aged 71, of coronary occlusion.

Edward Hilts Ewing, Stoughton, Mass.; College of Physicians and Surgeons, Baltimore, 1897; member of the American Medical Association; served during World War I; associate medical examiner for the Norfolk County fifth district; formerly a member of the school committee in Stoughton; died March 8, aged 74.

LeRoy Ellis Fosner ⊕ Evanston, Wyo.; Maryland Medical College, Baltimore, 1911; secretary of the Uinta County Medical Society; served as mayor, county health officer and county physician; died April 21, aged 61, of cerebral hemorrhage.

Edward Frank Freedman, Cleveland; Western Reserve University School of Medicine, Cleveland, 1913; specialist certified by the American Board of Radiology; member of the Radiological Society of North America; affiliated with the Mount Sinai Hospital, where he died April 16, aged 59, of coronary thrombosis.

Frederick Joseph Garlick ⊕ Rochester, N. Y.; Albany Medical College, 1911; member of the American Urological Association; served overseas during World War I; consultant, Rochester State Hospital; served on the staff of the Monroe County Hospital; chief urologist, Park Avenue Hospital and the Rochester General Hospital, where he died April 22, aged 59, of arteriosclerotic heart disease.

Coleman P. Gay, Geneva, Ala.; Southern Medical College, Atlanta, 1897; member of the American Medical Association; past president of the Geneva County Medical Society; killed April 19, aged 73, when his automobile collided with a truck.

Lemuel B. Gilbert, McMinnville, Tenn.; Chattanooga (Tenn.) Medical College, 1903; died in the Rutherford Hospital, Murfreesboro, April 11, aged 72, of leukemia.

Herman Gliboff, Rockaway Beach, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1919; member of the American Medical Association; school physician; on the staffs of the St. Joseph Hospital in Far Rockaway and the Rockaway Beach Hospital; died in the New York Hospital April 13, aged 53, of carcinoma of the pancreas.

Rush Clayton Godfrey, Lancaster, Wis.; University of Pennsylvania School of Medicine, Philadelphia, 1912; member of the American Medical Association; past president of the Grant County Medical Society; served during World War I; physician in charge of the Grant County Asylum and medical director of the Lancaster General Hospital; died April 14, aged 61, of chronic myocarditis and arteriosclerosis.

Frank Goldenberg, Cincinnati; University of Cincinnati College of Medicine, 1914; on the staff of the Jewish Hospital; died April 16, aged 60, of coronary thrombosis.

Bernhard Alexander Goldmann ⊕ Pittsburgh; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1922; assistant professor of dermatology at the University of Pittsburgh School of Medicine; specialist certified by the American Board of Dermatology and Syphilology; member of the American Academy of Dermatology and Syphilology; on the staffs of the Woman's Hospital and the Presbyterian Hospital, where he died April 7, aged 51, of coronary disease.

William T. Griggs, Poplar Branch, N. C.; University of Virginia Department of Medicine, Charlottesville, 1896; member of the American Medical Association; served as assistant surgeon in the U. S. Public Health Service; died April 9, aged 80, of arteriosclerosis and heart disease.

August Groman, Odebolt, Iowa; Chicago Homeopathic Medical College, 1878; member of the American Medical Association; died April 22, aged 90, of angina pectoris.

Malcolm C. Guthrie ⊕ Kingston, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1907; formerly on the consultant staff of the Wilkes-Barre (Pa.) General Hospital; died April 14, aged 65, of heart disease.

John Franklin Habermel ⊕ New Albany, Ind.; University of Louisville School of Medicine, 1928; fellow of the American College of Surgeons; member of the staff of St. Edward's Hospital; died in St. Joseph's Infirmary, Louisville, April 4, aged 47, of acute bacterial endocarditis.

Chris Richard Halloran ⊕ Los Angeles; University of Texas School of Medicine, Galveston, 1923; member of the American Academy of Dermatology and Syphilology; for many years secretary of the Los Angeles Dermatological Society; died March 8, aged 50.

Robert Samuel Harwood ⊕ Los Angeles; Chicago College of Medicine and Surgery, 1915; died in March, aged 58.

Forest Jacob Isenberger, Gypsum, Kan.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1908; died in Topeka March 25, aged 78, of cerebral hemorrhage.

Lewis Turner Jackson, Tulsa, Okla.; St. Louis College of Physicians and Surgeons, 1906; died March 31, aged 69, of influenza.

George Howard Jantzen ⊕ Queens Village, N. Y.; Fordham University School of Medicine, New York, 1920; examining physician for St. Anne Council, Knights of Columbus; on the staffs of the Queens General Hospital, Jamaica Hospital and the Mary Immaculate Hospital in Jamaica, where he died April 2, aged 51, of nephritis.

Frederick Henry Johanboeke, Louisville, Ky.; University of Louisville Medical Department, 1896; also a graduate in pharmacy; member of the American Medical Association; died in the Kentucky Baptist Hospital April 4, aged 86, of arteriosclerosis and chronic lymphatic leukemia.

Edward Samuel Johnston, Cincinnati; Cincinnati College of Medicine and Surgery, 1898; died April 20, aged 79, of acute congestive heart failure.

Frank Benedict Keleher, Brooklyn; Long Island College Hospital, Brooklyn, 1895; affiliated with St. Mary's Hospital, where he died April 18, aged 73, of perforated duodenal ulcer and general peritonitis.

Clarence Fay Kercheval, Clinton, Ind.; Illinois Medical College, Chicago, 1898; died April 2, aged 74, of chronic emphysema.

George Morris Kersey, Atlanta, Ga.; Meharry Medical College, Nashville, Tenn., 1940; interned at the Freedmen's Hospital in Washington, D. C.; served a residency at the Trinity Hospital in Detroit; a captain in the medical corps, Army of the United States, during World War II, serving as an associate medical officer at the Veterans Administration Facility in Tuskegee, Ala.; died April 16, aged 34, of dissecting aneurysm of the aorta.

Robert Kettner, Denver; University of Nashville (Tenn.) Medical Department, 1890; also a dentist; died in Albuquerque, N. M., March 1, aged 86, of cerebral hemorrhage.

Drue King, Tuskegee, Ala.; Tufts College Medical School, Boston, 1914; for many years affiliated with the Veterans Administration Hospital, where he died April 20, aged 60, of cerebral hemorrhage.

Russell Henry King, Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1904; served during World War I; affiliated with the St. John's General Hospital; died April 24, aged 68, of coronary thrombosis.

Harold William Klewer, Toledo, Ohio; University of Cincinnati College of Medicine, 1935; member of the American Medical Association; interned at the Lucas County General Hospital; served in the medical corps of the U. S. Naval Reserve during World War II; on the staffs of the Maumee Valley Hospital, Toledo Hospital and the Mercy Hospital, where he died April 17, aged 40, of uremia.

Boyden Waclaw Kowalski ⊕ Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1928; honorary deputy sheriff of Ocean County, N. J., died April 9, aged 43, of carcinoma of the bronchus.

Frank George Kreft, Toledo, Ohio; University of Cincinnati College of Medicine, 1915; for many years county coroner; served during World War I; on the staff of St. Vincent's Hospital, where he died April 9, aged 56, of subarachnoid hemorrhage.

James Wesley Krichbaum, Montclair, N. J.; the Hahnemann Medical College and Hospital, Chicago, 1891; served on the faculty of the New York Homeopathic Medical College and Flower Hospital in New York; formerly on the staff of the Montclair Community Hospital; died April 22, aged 85, of cardiac decompensation and arteriosclerosis.

Charles Edward Lambert, New York; Bellevue Hospital Medical College, New York, 1893; died in St. Luke's Hospital April 6, aged 80, of arteriosclerosis and pneumonia.

Jennie Theodate Miner Lane, Worcester, Mass.; Boston University School of Medicine, 1896; died April 9, aged 86, of cerebral arteriosclerosis.

Damon Smith Latimer, Union City, Tenn.; University of Tennessee College of Medicine, Memphis, 1917; member of the American Medical Association; formerly secretary of the Obion County Medical Society; died in the Baptist Hospital, Memphis, April 26, aged 52, of cerebral hemorrhage.

William George List, Cincinnati; Medical College of Ohio, Cincinnati, 1896; member of the American Medical Association; at one time on the faculty of his alma mater; on the courtesy staff of the Jewish Hospital, where he died April 4, aged 71, of influenzal meningitis.

Philip Coe McDowell ⊕ Wooster, Ohio; Western Reserve University School of Medicine, Cleveland, 1918; fellow of the American College of Surgeons; formerly in charge of the American Presbyterian Mission, Tehran Hospital, Tehran, Iran; died April 10, aged 55, of coronary thrombosis.

William Peter Martin ⊕ South Orange, N. J.; Baltimore University School of Medicine, 1902; died in the Hospital of St. Barnabas in Newark April 2, aged 77, of chronic glomerulonephritis, diabetes mellitus and uremia.

Emery Allen Paschal, St. Charles, Ill.; Rush Medical College, Chicago, 1879; died in the Delnor Hospital April 2, aged 90, of pneumonia.

Frances L. Patrick, Chicago; Northwestern University Woman's Medical School, Chicago, 1894; died April 12, aged 86, of chronic myocarditis.

Theodora Garthwaite Tucker Peck, Elizabeth, N. J.; New York Medical College and Hospital for Women, Homeopathic, New York, 1900; died in the Richmond Memorial Hospital in Staten Island April 4, aged 69, of arteriosclerotic heart disease and pulmonary infarction.

Alexander C. Peska ⊕ Chicago; Loyola University School of Medicine, Chicago, 1922; on the staff of the Lutheran Deaconess Hospital; died April 9, aged 58, of coronary occlusion.

Stephen J. Podlewski, Steubenville, Ohio; Baltimore Medical College, 1895; member of the American Medical Association; vice president of the Peoples National Bank; for many years surgeon for the Pennsylvania Railroad Company; on the staff of the Gill Memorial and Ohio Valley hospitals; died April 8, aged 74, of heart disease.

Adolf Hans Potthast ⊕ Weimar, Texas; University of Texas School of Medicine, Galveston, 1915; physician for the Selective Service during World War I and II; served as city health officer; died in the Medical and Surgical Memorial Hospital in San Antonio, April 24, aged 57, of a malignant tumor.

Dominic Antonio Puleo, New York; Georgetown University School of Medicine, Washington, D. C., 1920; member of the American Medical Association; died April 19, aged 54.

Frederick Carver Robbins, Canandaigua, N. Y.; Boston University School of Medicine, 1896; member of the American Medical Association and the American Psychiatric Association; served during World War I; lieutenant colonel, medical reserve corps, not on active duty; at one time affiliated with the Cornell University in Ithaca; served on the staffs of Veterans Administration facilities in various places; on the staff of the Brigham Hall Hospital; died in Tampa, Fla., April 16, aged 73, of coronary occlusion.

W. Arch Robinson, Sturgeon, Mo.; Barnes Medical College, St. Louis, 1898; member of the American Medical Association; died April 10, aged 71, of myocarditis.

William Campbell Roland, Indianapolis; Kentucky School of Medicine, Louisville, 1893, veteran of the Spanish-American War and World War I; died in Fort Harrison, Ind., March 2, aged 78, of cerebral thrombosis and arteriosclerosis.

Edward Gould Rowland, Trenton, N. J.; Baltimore Medical College, 1903; specialist certified by the American Board of Psychiatry and Neurology, Inc.; member of the American Psychiatric Association; served on the staffs of the Norwich State Hospital in Norwich, Conn., Madison State Hospital in North Madison, Ind., and the New Jersey State Hospital; died in Philadelphia April 9, aged 68, of lymphosarcoma.

Abigail A. Shortess Ruston, Evansville, Ind.; Physio-Medical College of Indiana, Indianapolis, 1900; died April 28, aged 77, of hypertensive heart disease and hypostatic pneumonia.

Walter R. Shannon ⊕ Milford, Pa.; Baltimore University School of Medicine, 1897; past president of the Wayne-Pike Counties Medical Society; county medical director; examining physician for the county Selective Service during World War II; on the courtesy staff of St. Francis Hospital in Port Jervis, N. Y.; at one time surgeon for the Erie Railroad and a member of the state legislature; died in Allentown April 7, aged 71, of coronary occlusion.

William Henry Shields, Ellwood City, Pa.; Medico-Chirurgical College of Philadelphia, 1893; on the staff of the Ellwood City Hospital; died in the Shadyside Hospital in Pittsburgh April 24, aged 78, of coronary occlusion, hypertension and cerebral hemorrhage.

Mayer Shoyer, Holton, Kan.; University Medical College of Kansas City, Mo., 1897; member of the American Medical Association; county health officer; affiliated with St. Francis Hospital in Topeka; died April 5, aged 71, of sarcoma of the liver.

Elijah W. Smith, Benton Harbor, Mich.; Indiana Eclectic Medical College, Indianapolis, 1890; Barnes Medical College, St. Louis, 1893; formerly associated with the Indian Service; died March 30, aged 89, of pneumonia.

Carlos C. Stevens ⊕ Blytheville, Ark.; University of Georgia Medical Department, Augusta, 1902; on the staff of the Blytheville City Hospital, where he died March 23, aged 68, of heart disease.

Jesse Oldham Strother ⊕ Henderson, Ky.; Kentucky University Medical Department, Louisville, 1905; on the staff of the Deaconess Hospital in Evansville, Ind.; member and past president of the staff of the Henderson Hospital, where he died April 21, aged 65, of coronary thrombosis.

Reginald James Henry Stroud ⊕ Tempe, Ariz.; University of Colorado School of Medicine, Denver, 1912; served as secretary and state superintendent of public health; member of the House of Delegates of the American Medical Association from 1919 to 1930; formerly affiliated with the Indian Service; past president of the Maricopa County Medical Society and the Cochise County Medical Society; commissioner for the Amateur Athletic Union; formerly affiliated with the Cochise County Hospital at Douglas; served on the staffs of the Southside District Hospital in Mesa, St. Joseph Hospital and Good Samaritan Hospital in Phoenix, where he died April 4, aged 60, of cholelithiasis, hepatitis and diabetes mellitus.

Anna E. Daniels Trimble, Middleport, Ohio; Cincinnati College of Medicine and Surgery, 1896; died March 12, aged 78, of cerebral embolism.

Thomas Francis Welch, Washington, D. C.; Georgetown University School of Medicine, Washington, 1922; interned at the Central Dispensary and Emergency Hospital; died in Towson, Md., April 5, aged 48, of pulmonary tuberculosis.

Frank Moore Whiting, Oroville, Calif.; Cooper Medical College, San Francisco, 1906; served during World War I; deputy county health officer; died April 26, aged 71, of carcinoma.

Creed Scott Wilkins, Abbeville, Miss.; Memphis (Tenn.) Hospital Medical College, 1911; director of the First National Bank of Oxford; died March 16, aged 59, of heart disease.

James Edgar Wilson, Lancaster, Texas; University of Texas School of Medicine, Galveston, 1896; at one time assistant health officer of Dallas; served during World War I; during World War II examining physician for the local draft board; served on the local school board; died March 8, aged 73, of coronary occlusion.

William Francis Wood, Bedford, Va.; College of Physicians and Surgeons, Baltimore, 1893; died April 19, aged 84, of myocarditis.

Daniel Yellin, San Francisco; University of California Medical School, San Francisco, 1939; member of the American Medical Association; affiliated with the Mount Zion Hospital, where he died March 5, aged 32, of lupus erythematosus.

June 14, 1947.

First Step in Organizing the National Health Service

The National Health Service is now law, but the organization of a medical service for every person, which includes every form of treatment, general practitioner, consultant and hospital, is a gigantic task which has only begun. As a first step the executive councils regulations have been laid before Parliament by the minister of health. The act envisages the setting up of executive councils in each county and county borough to organize the family practitioner services locally. The regulations deal with arrangements for appointing members, terms of office, and general procedure. Half the membership of the councils is to be professional and appointed by the medical profession itself, and half is to be appointed by the local health authorities and the minister. The regulations provide for the annual retirement of one third of the members and thus set up the normal term of office as three years. Most of the appointments to the first executive councils have already been made by the local authorities and the local medical organizations, and the minister of health is now considering what appointments he will make.

The executive councils will not only have to begin planning the services for which they will themselves be responsible but they will also have to give any advice or help sought by bodies responsible for organizing other parts of the service, such as local health authorities and the regional hospital boards. The regulations also provide for the appointment by these councils of ophthalmic services committees which will organize the local supplementary eye service, which is to be provided by physicians with prescribed qualifications and by ophthalmic and dispensing opticians. It is hoped that the health service will come into operation next April.

Poisoning by Dried Egg

During the war the importation of spray dried egg was a valuable means of economizing shipping space. But a number of cases of poisoning due to Salmonella organisms occurred. This has led the Medical Research Council to make an investigation, the result of which is published in a pamphlet entitled "The Bacteriology of Spray Dried Egg, with Special Reference to Food Poisoning." Examination of 7,584 samples of dried egg showed the presence of Salmonella organisms in 9.9 per cent. In 1944 the number of known outbreaks of food poisoning due to Salmonella reached the unprecedented total of 454, a figure greater than that for seventeen years preceding the war.

Between 1942 and the end of 1945, 244,000 tons of dried eggs were imported from the United States, Canada and the Argentine. Though the risk of food poisoning was apparent, consumption continued because of the high value as a concentrated foodstuff. Dishes of dried eggs were prepared in the experimental kitchen of the Ministry of Food and tested at the bacteriologic laboratory at Cambridge. It was proved that dried egg was safe to eat if cooked soon after reconstitution, even by such a relatively mild heat treatment as scrambling. Recipes for custard sauces prepared without boiling and milk and egg shakes were rejected.

Gift for Repair of the Royal College of Surgeons

A gift of $40,000 from the American College of Surgeons has been received by the president of the Royal College of Surgeons as a contribution to the fund for the restoration of the Royal College so extensively damaged in 1941 by German bombs. This gift brings the total so far received to $700,000 toward the $1,000,000 required. The American College is also giving a desk and lantern for the lecture theater of the Royal College.

To Reintroduce Bill to Legalize Euthanasia

The Voluntary Euthanasia Society, which introduced a bill in the House of Lords to legalize euthanasia for patients suffering intolerable pain from incurable disease, has held its annual meeting. The bill was presented in 1936 but failed to secure a second reading. At the meeting Dr. E. A. Barton, who had retired after forty years' practice in London, said that doctors who acceded to a patient's appeal for release took a risk. Though cases needing euthanasia are rare—he had seen only half a dozen in fifty years—they were peremptory. He hoped that many would be willing to risk criticism and worse by doing for the patient what they would wish to be done for themselves in similar circumstances. The society proposes to reintroduce the bill. It is suggested that England should be divided into areas, in each of which two doctors of high standing should be appointed who could be called on by the general practitioner to carry out the final act. The patient would have to ask for the relief, but only urgent pleas would be considered. The consent of the friends would not be asked, for, if refused, the patient must continue to suffer, and if it was given, misunderstandings might arise later. Though euthanasia is not legal, the authorities do not seem disposed to take any action in the cases in which relief has been given.

Sir Almroth Wright

The death of Sir Almroth Wright at the age of 85 has removed from medicine a great and unique figure. The son of an Irish father and Swedish mother, he was educated at Trinity College, Dublin, where he graduated B.A. in 1882 and won the gold medal in modern literature. He had already taken up medicine, in which he graduated in 1883. His pioneer work on immunization began in 1896. Inspired by Haffkine's inoculation of cases of cholera and Pfeiffer's inoculation of 2 cases of typhoid, Wright introduced the idea of immunization by vaccines made of killed bacteria. Pasteur had obtained results by inoculation of living but attenuated cultures. Wright, however, thought that inoculation of living microbes to produce immunity in man would not be practicable on a large scale. He therefore perfected the technic of inoculation of killed typhoid cultures and showed that they would protect against the disease. He then came up against the opposition of the army authorities, whose conservatism could not stomach the novel idea of introducing microbes, dead or alive, into the human body. So powerful was the opposition that he had to resign his army post. However, a supply of his vaccine was dispatched with the troops sent to South Africa to fight the Boers. There, as in other campaigns, typhoid was rife, owing to insanitary conditions in a dusty climate, which led to a plague of flies as carriers. The results were most satisfactory. Wright was able to show that at Ladysmith only 2 per cent of 1,705 men who had been inoculated contracted typhoid, while 13.2 per cent of those not inoculated did. A similar result was obtained in troops stationed in India. The result was that the War Office adopted typhoid inoculation as a routine procedure.

In 1902 Wright obtained his most important appointment, which he held nearly to the end of his life—pathologist to St. Mary's Hospital, London. Under his direction a special department was created, the Department of Therapeutic inoculation, which afterward became the Institute of Pathology and Research. The institute provided sufficient antityphoid vaccine for 4½ million men. His work centered on the possibility of controlling bacterial diseases already in progress by inoculation of killed cultures (vaccines). He was not content to measure the results clinically. He examined the patient's blood for indications that the body had responded by the production of protective substances. This led to new technical procedures for the measurement of phagocytosis and bactericidal power, which he embodied in a book published in 1912 entitled "Technique of the Teat and the Capillary Glass Tube." It was an important first step in the application of micro-technic to bacteriology.

Sir Frederick Gowland Hopkins

The death of Sir Frederick Gowland Hopkins in his eighty-sixth year has removed the man who played the greatest part in the creation of the science of biochemistry. He is most widely known as the discoverer of the vitamins, but his other fundamental research included the part played by lactic acid in muscle activity, the discovery of the amino acid tryptophan and its "specific biologic value," and the isolation of the cell catalyst glutathione. His scientific life began with the study of chemistry. The government analyst and medical jurist Sir Thomas Stevenson appointed Hopkins his assistant. He showed great skill in the isolation and identification of poisons in famous criminal cases. He next studied medicine and qualified but never practiced. His chemical training directed him toward pathologic research. In 1896 he was largely instrumental in the founding of the Clinical Research Association, an entirely new kind of undertaking which examined pathologic specimens for physicians and reported on them. Toward the close of the century came a turning point in his career. He attracted the notice of the physiologist Sir Michael Foster, who occupied the chair at Cambridge and invited Hopkins to go there and develop teaching and research in the chemical side of physiology. He was appointed lecturer in chemical physiology and had not been long at Cambridge when, in 1901, he made his first great discovery. In collaboration with S. W. Cole he isolated the amino acid tryptophan. In 1914 a professorship in biochemistry was created for him. In his later years he took an active part in the direction of scientific research. He was an original member of the Medical Research Council. In 1931 he was elected president of the Royal Society, the highest scientific position in this country. Under him the Cambridge School of Biochemistry became famous for investigations into the chemistry of life. Visitors came to his laboratory from all over the globe and went away impressed by the man and his work.

Poliomyelitis in France

The following figures show that poliomyelitis has lately attained importance among infectious diseases in France:

Year	Months	Number of Cases
1943	June to November	1,800
1944	June to November	366
1945	June to November	780
1946	June to November	1,342

Two small epidemics are to be noted during the years 1943 and 1946. In the period from the 1st of January to the 1st of May 1947, 182 cases have been recorded, and the Bulletin of Epidemiologic Information of the Ministry for Public Health states that "these figures surpass the average and remain close to the maximum of cases noted in the course of ten years."

The 1943 Epidemic

This epidemic began at Montluçon and had two foci, one in the Allier and Haute-Garonne departments, the other in the Meurthe-and-Moselle department. Its chief characteristics were that (1) in addition to 1 to 6 year old children a number of adults and adolescents were stricken, (2) cases with early meningeal symptoms were rare and (3) the paraplegic and monoplegic forms were prevalent (65 per cent). The mortality rate was 10.5 per cent.

The 1946 Epidemic

This epidemic produced 51 cases in June, 155 cases in July, 335 cases in August, 376 cases in September, 278 cases in October and 127 cases in November. It had one focus in the department of Maine-et-Loire and, generally speaking, in the regions bordering on the Loire River, between Saumur and Angers, and another focus in the Côte d'Or, in the Beaune district. As in 1943, the epidemic did not affect Paris. All cases reported for Paris have been sporadic or those of adults and children, who appear to have contracted the disease in the other infected areas or who had been in contact with infected persons and came back to Paris during the incubation period. While the river Seine cannot be considered as a source of contagion, nevertheless the prohibition of bathing in rivers was one of the first prophylactic measures taken. The epidemic was characterized by the existence of typical paralytic cases, but there were also atypical cases with meningeal or encephalic syndromes. Paralleling this poliomyelitis epidemic, encephalitis was noted in horses, as well as other epidemics in chickens. All efforts, including laboratory studies of those animal diseases, made with a view of discovering the origin of poliomyelitis, have given no result.

At several meetings of the National Academy of Medicine, Debré, Lemierre and Levaditi discussed the means of transmission of poliomyelitis. Debré and Lemierre voiced doubts regarding its propagation by the enteral route, but Levaditi upheld this theory. In discussing respiratory failure in poliomyelitis, Debré emphasized that, in the case of serious paralysis of the respiratory muscles, the prognosis does not improve as a result of artificial respiration provided in the steel lung.

Sanitary Condition in the Overseas Territories

A special meeting April 29 of the National Academy of Medicine, under the presidency of Mr. Jolly, was devoted to exotic pathology. General A. Sice, inspector of colonial troops, presented a survey of the present health condition of French overseas territories. Thanks to the efforts of the Service of General Hygiene, improvement in the cultivation of foodstuffs has taken place. A stubborn fight against the state of underfeeding of the population has increased the resistance of the people against infections by restoring alimentary equilibrium. As a consequence a decrease in epidemics, once murderous, has been recorded. Smallpox has been kept in check everywhere. In 1943 a local epidemic brought by nomads made its appearance at Fort Lamy; the situation was straightened out after 626,873 smallpox vaccinations and 78,921 associated vaccinations with a vaccine produced in the vaccination center of Fort Lamy, under control of the Brazzaville Pasteur Institute, had been effected. Human trypanosomiasis, which formerly destroyed the population of entire villages, is regressing. In French West Africa, out of 4,500,000 inhabitants examined, 300,000 were found ill and treated. In French Equatorial Africa, out of a population of 3,800,000 inhabitants, 1,472,700 were examined, among whom 7,600 were found ill. Paludism, especially in Madagascar and in La Réunion Island, is not yet checked. In 1945 Madagascar alone had 777,000 cases. Leprosy is progressing, on account of the lack of hygiene, in the zones where the disease is endemic. Plague is regressing and the number of cases, which was 681 in 1939, was 184 in 1945; 3,000,000 vaccinations were performed with the living vaccine prepared by Girard at the Tananarive Pasteur Institute.

Yellow fever is also decreasing. In West Africa, 23 cases were recorded in 1941; there were only 2 in 1944. Since 1941, in Free French Africa, anti-yellow fever vaccination has been declared compulsory. The number of persons subjected to vaccination increased from 8,000,000 in 1941 to 15,000,000 in 1945. Syphilis still exerts its nefarious influence on infantile mortality. As to the experimental work of the branches of the Pasteur Institute, especially to be noted is the importance of a polyvalent anti-snake bite serum of the Brazzaville Pasteur Institute. This is very effective against the venoms of Naja melanoleuka and of Dendropsis jameson. A permanent commission for anthropologic studies of the aborigines of Africa has been created to study their migrations and their intermixtures.

National Surgical Congress

The first postwar national surgical congress was held in Florence at the same time as that for internal medicine. Professor Pedotti, chairman of the Swiss Surgical Society, and Professor Datymer, representing the surgeons of Poland, participated.

The first joint session with the medical association was devoted to papers on tumors of the colon. Professor Alessandrini of the University of Rome presented a paper from the medical point of view, Professor Matronola of Rome from the surgical point of view, and Professor Cignolini of Genoa from the roentgenologic point of view.

Professor Alessandrini's paper was devoted particularly to epithelioma's of the colon and to their early diagnosis; he emphasized the progressive increase of these neoplasms as demonstrated by clinical and anatomicopathologic statistics. According to the speaker the continued use of laxatives with liquid petrolatum as a base or of derivatives of anthracene or phenanthrene for years or decades may be considered as one of the causes of the increase. With regard to therapy, surgical intervention may be the method of choice as soon as the diagnosis of epithelioma of the colon has been established; it should be preceded by adequate medical preparation (rational irradiation, insulin therapy, occasionally blood transfusions, sulfonamide therapy). The opportunity of surgical intervention for diffuse polyposis is controversial. A substantial diet is suggested for inoperable cases; it should be poor in cellulose, in fats and in sodium chloride but rich in potassium.

In discussing surgical intervention, Professor Matronola stated that the first step should be exploratory, consisting in an extensive laparotomy which allows for examination of the internal abdominal cavity. The location and the extent of the tumor should be established on exploration as well as the occurrence of adjacent or distant metastases, and it should be decided whether the removal of the tumor will be feasible. In case it should not be feasible, one may resort to a palliative operation, i. e. an internal derivation (anastomosis) or an external one (artificial anus). Hemicolectomy may be performed as a radical operation for cancer of the right colon, but there is no agreement with regard to one or two stages. According to the speaker, intervention in two stages may be generally preferred. There is no consensus with regard to the method of choice for intervention of cancer of the transverse colon: segmentary resection, the Mikulicz operation, hemicolectomy. The mortality rate is high. More difficult problems may be presented to the surgeon by the left colon. For cancer of the left angle and of the descending colon, left hemicolectomy may be preferred in most cases, preceded by a cecal anus and followed by transverse sigmoidostomy. Cancers of the sigmoid flexure may easily be extirpated because of the length of the mesentery. The simplest and safest method of treatment of epithelioma of the rectosigmoid consists in low amputation, which may be terminated by a definite iliac anus. The operative mortality rate has been reduced to a negligible percentage.

Professor Cignolini demonstrated the great difficulties met on x-ray examination of the colon. He stressed the notable parallelism between the neoplastic symptomatology of the colon and that of the stomach. The greatest difficulty in establishing a differential diagnosis between intestinal and gastric forms results from the fact that the pathology of the colon is much more variable than that of the stomach. With the aid of the technic of intestinal intubation it becomes possible in many cases to localize and to define the obstructional lesion.

Trauma of the Thorax

Professor Gherardo Forni of the University of Bologna demonstrated that the thoracic viscera may be exposed to violent and highly complex traumatism because of their plurality and their vital functions. The symptoms vary according to the anatomic lesion and the intensity of the trauma. Pain may be predominant in parietal contusions with skeletal lesions and may be exacerbated with respiration. Pulmonary and cardiac lesions may be manifested by cough, blood in the sputum, dyspnea, cyanosis, tachycardia and arrhythmia. X-ray examination is of great significance for demonstrating a displacement of the viscera, the loss of their normal relationship and the occurrence of fluid or gas in the pleural and pericardial cavities. Surgical intervention may be required by the occurrence of a hypertensive pneumothorax, of a generalized emphysema spreading to the mediastinum or by a profuse hemothorax. It presents excellent therapeutic judgment in case of profuse and threatening hemothorax to remove the blood and to induce a pneumothorax (Morelli). A pneumothorax of mild degree may not require any treatment; in pneumothorax with high tension, puncture may be performed. Bilateral pneumothorax, which presents a serious threat to the life of the patient, requires immediate intervention: puncture of the thorax and occasionally thoracotomy with suture of pulmonary lacerations. In generalized emphysema with cyanosis and progressive asphyxia a suprasternal incision may be made and an aperture of the mediastinum with application of drainage by means of a cupping glass.

Cancer of the Uterus

Professor Antonio Biancheri believes that subtotal hysterectomy may be the treatment of choice in all cases in which removal of the uterus may be required for fibroma or for connected causes in the absence of any involvement of the cervix. In those cases, however, in which the cervix presents lesions from which suspicions of a precancerous condition may arise it may be necessary to remove the mucosa or the involved segment of the cervix by means of electrocoagulation or by the application of radium. In cancer associated with pregnancy, Wertheim's operation remains the method of choice according to the statistics of Italian gynecologists.

Professor Luigi Caravani believes that the symptoms which had been considered as an initial manifestation of cancer of the body of the uterus should be interpreted as one of a spreading process of the already present blastomatous permeation of the entire female genital system. Consequently he suggested total colpohysterectomy by the abdominoparavaginal route, with the removal of the entire genital complex and all the glands connected with it. The speaker contrasted the high postoperative mortality rate (actually about 28 per cent, but with a possibility of being reduced with improved technic) with the high percentage (better than 80) of permanent recovery in women with cancer who received similar treatment.

Professor Eugenio Milani emphasized that the guiding line for radiologic treatment of cancer of the cervix of the uterus should be in general that endocavitary Curie therapy may be combined with transcutaneous roentgenotherapy. A two stage treatment may be effective in the majority of cases, but there are also workers who favor simultaneous treatment. A combined treatment may likewise be the guiding line for radiologic treatment of the body of the uterus in all the inoperable cases as well as in those that have passed the first stage. For the operable cases the statistics demonstrate that the percentage of a five to ten year recovery may be higher if surgical intervention can be combined with postoperative roentgenotherapy. The treatment of recurrence and metastasis may be essentially radiologic.

Executive Committee

The new executive committee of the Italian Surgical Society was elected with Professor Luigi Torraca as president.

The subjects for papers at the next congress are (1) surgical treatment of pulmonary tuberculosis, (2) surgical treatment and treatment with estrus producing compounds for cancer of the prostate, (3) cicatricial stenosis of the esophagus and (4) (in cooperation with the Italian Society of Internal Medicine) mediastinal syndromes.

Antituberculosis Vaccination

The work of Soviet scientists begun in 1925 demonstrated that Calmette's antituberculosis vaccine decreases the mortality among vaccinated children from two to four times. Those figures are based on prewar data when about three million children were vaccinated—more than in all other countries of the world. Weisfeiler and his collaborators demonstrated that Calmette-Guérin bacillus efficiency during parenteral administration is much higher when used twice. Professor Pokrovskaya showed the possibility of vaccine intensification by means of a nonspecific mesenchymotropic preparation. Khmelnitskaya and Rabinovich found that small doses of Calmette-Guérin bacillus used subcutaneously have in certain types of tuberculosis a curative effect. Weisfeiler, Baydakov and Tourgetsky could not confirm Calmette's observations on the rapid destruction of their bacillus in the vaccine fluid. If it is obtained from young cultures, its immunizing properties are preserved about one month. In 1937 Weisfeiler reported on obtaining a dry vaccine with a longer expiration date. His collaborator Leschinskaya worked out a method of preparing a dry glucose vaccine, and it has been used since 1943, when the people of distant areas and regions released from fascist occupation were immunized with the dry glucose vaccine. Great Britain has begun experiments with the dry vaccine, based on the Soviet method.

At present methods for obtaining a more potent vaccine are being worked out, and a search is being made for new cultures with high immunizing properties. Exact experimental figures are being collected on the grade of high quality dry vaccine and on optimal conservation conditions for the Calmette-Guérin bacillus in dry form.

Acclimatization of Residents in the Arctic Regions

The aim of the expedition in the arctic region of two Institutes of the Academy of Medical Sciences of the U. S. S. R.—General Hygiene and Nutrition, in 1946, was a mass observation of the population. It was noted that inhabitants of Northern regions, become accustomed to a new environment best of all—those from middle and central parts of the Soviet Union do so with some difficulty—and natives of the South do so worst of all. In this climate the time of work is changed four times yearly because of the long polar night. Nearly 80 per cent of the residents after arriving suffer from nostalgia, which completely disappears when people are busy working.

The morbidity in the arctic is less than in the other parts of the Soviet Union. Living in conditions of eternal frost results in freezing of the feet even during summer because the soil layer (exposed to melting) does not exceed 40 cm. Wounds close without suppuration because of the sterility of the air and small virulence of micro-organisms. Comparatively frequent is appendicitis. Arthralgia occurs with the low temperature but without objective changes in the joints. Heart and blood vessel diseases are quite rare. Caries is very common; it spreads quickly and is accompanied with pyorrhea. One of its possible causes is the use of demineralized snow water.

The investigators find that the arctic climate will have a favorable influence. The polar night is characterized by many factors having a stimulating influence—electrical status of the atmosphere and presence of enormous quantities of ionized air rich with ozone. The polar radiation also is stimulating. The first objective is to organize a work and rest regimen in order to maintain a normal physiologic rhythm.

Again this year, expeditions of scientific institutes in the arctic region are taking place to study the mechanism of the acclimatization processes.

Visceral Leishmaniasis (Kala-Azar)

Nicholas I. Latichev of the Institute of Epidemiology and Infectious Diseases of the Academy of Medical Sciences of the U. S. S. R. has reported a study of visceral leishmaniasis. In 1940 in Middle Asia about 2,000 cases were identified and in the Precaucasus about 500. Thus kala-azar takes an insignificant place among other diseases, in our country, especially in comparison with India, where it sometimes takes on the character of an epidemic.

During the building works in 1933 in the valley of the Waczch River (South Tajikistan) there were a number of cases of "chinidine resistant malaria without parasites in the blood," which were later identified as visceral leishmaniasis. When the epidemiology of the disease was studied the jackal was suspected as a reservoir of the virus and it became necessary to demonstrate the existence of spontaneous infection in those animals. In 1946 in the liver and spleen of some jackals killed in the lower parts of Kafirjagan River Leishmania was identified. On the basis of these facts Latichev finds that visceral leishmaniasis is not a simple infection but has three different types. The first is a zoonosis affecting rural populations which are infected from natural reservoirs of the virus—jackals and stray dogs. The second type, anthroponosis, is found in towns where the principal source of infection is the patient and dogs are only a minor factor. The cause of the third type, Indian kala-azar, is closely connected with the human organism.

Institute of Gynecology and Obstetrics

At the third session of the Institute of Gynecology and Obstetrics of the Academy of Medical Sciences of the U. S. S. R. Professor E. Berkovich and his associates reported a study of placental substances influencing the mechanism of labor. They found that the placenta contains a large amount of acetylcholin which the placenta synthesizes. Its action is accelerated by vitamin B_1 and pituitary, which sensitize the uterine muscle. However, when verifying the action on the uterus of potassium, calcium, thiamine and pituitary it was demonstrated that its oxytocic effect is rather small. Thus the authors conclude that the blood oxytocic properties of lying-in women depend on acetylcholine circulating in their blood and diminution of cholinesterase.

Professor G. Salgannic and his associates spoke on the excitability of sensory centers of pregnant women. An increase of cerebral excitability of the optical centers at the sixth month and one to two weeks ante partum was observed. During labor excitability of the cerebral sensory centers is decreased and soon after delivery reaches its usual figures. For evaluating the status of the vegetative, nervous and reticuloendothelial systems much clinical material was studied. During the second period of pregnancy and labor sympathicotonic symptoms are present; simultaneously the reticuloendothelium is depressed; only in certain cases can a total vegetative dystonia be observed. These observations demonstrate the influence of the protective systems in pregnant women and may be of use for increasing their resistance to infectious diseases.

The anesthetic and labor accelerating effect of thiamine reported by Professor R. Schub (The Journal, January 11, p. 122) was confirmed by dozent D. Ginodman and Drs. M. Tyurin and M. Ziroulnikov. They noted a parallelism between the content of vitamin B_1 in the organism, the duration of labor and labor pains. They were more frequent and powerful after thiamine administration. However, its anesthetic action is small.

MADRID

June 7, 1947.

Studies of the Spanish School of Cajal

The Spanish School of Histology and Pathology, which under S. Ramon y Cajal has become the pride of Spain, is still active in spite of all difficulties. The names of Pio del Rio Hortega (who died a year ago) and J. F. Tello are well known and some of their recent work merits description. Tello, Cajal's favorite pupil, is working in his old laboratory at the Cajal Institute (now incorporated in the Higher Council for Scientific Research and subsidized by the state) and, since 1942, has carried out studies on the structure of the tactile and motor nerve endings.

As a result of his studies on the motor endings of batrachians and reptiles he has been able to prove that in all animals examined the ramification of the axon in the motor endings of the voluntary muscles appears enveloped in a nucleated sheath, which seems to be the continuation of the sheath of Schwann. More recently he has published two studies on neurogenesis. In the first he reviews the genesis of the sympathicus by Bielschowsky's method in blocks and not only confirms his previous ideas on mesodermic origin but sees this forming at the expense of syncytial cords of endothelium, starting from the aorta and resembling vascular buds.

Of special interest, because it is an original and fundamental contribution to knowledge of the disputed problem of the neurogenesis of cranial ganglions, especially of the part played in them by the neural crest, is his latest published work. In it he deals with the respective participation of the neural crest and the placodes in the formation of the sensitive cranial nerves (in chickens), proving that most, if not all, of the nervous elements proceed from the ectodermic placodes subsequent to the disappearance of the crest. All these papers were published in the review *Trabajos del Instituto Cajal de Investigaciones Biológicas* between 1942 and 1946.

Importance also attaches to the work of Dr. F. de Castro, professor in Seville University, carried out in the Cajal Institute (Madrid). Continuing his investigations by his crossed anastomosis method, which makes it possible to model a simple bineuronal reflex arc, he has arrived at a new concept of the synapsis in centers and peripheral ganglions. In the modeling of the synapsis, three discontinuous active elements are concerned without any trophic continuity between them: the affector element, the effector element and the intermediary element (neuroglia), whose protoplasm, interposed between the other two, serves as an indispensable mediator of the nervous current. This is sometimes the Schwann cell, sometimes the intercapsular cell of the ganglion and sometimes again the oligodendroglia itself. The genetic and morphologic identity of these elements, already upheld by Pio del Rio Hortega and demonstrated by J. M. Ortiz Picon in the case of the ganglion cells, is verified by Rodriguez Perez in the case of the Schwann cell.

The doctrine of these Spanish authors is summed up in the concept of "tripolar synapsis," which offers a physiologic explanation of the polarization of current and the inhibition of the antidromic conduction at the level of the first intercalary station. These facts reinforce the thesis of the anatomic unity of the nerve cell.

Professor J. Sanz Ibañez, professor of histology and pathology in Madrid University, has carried out research on the experimental histopathology of poliomyelitis by Nissl's method and silver saturation. He studies the spinal medulla of mice, guinea pigs and monkeys with paralytic manifestations after virus infections and proves the existence of lesions of the central nervous system, above all in monkeys. But the fundamental change occurs in the peripheral nerves of the paralytic limbs (in the distal parts) and also in the myoneuronal synapsis, the thick nerve trunks being free from lesions. There are sometimes regenerative phenomena in the synapsis which, according to him, are evidence of the absence of central lesions, since that would not be possible if the spinal neuron was infected.

According to Sanz Ibañez the paralysis is of peripheral origin and is related to the motor plate, as is proved by the presence of viruses in the muscles of the paralytic legs of mice. He also studied the degenerative lesions of the liver, spleen, heart, kidneys, intestine and adrenals, which he attributes to the presence of virus in the blood. He describes clinical forms without paralysis or any neuraxial lesions and succeeds in adapting to guinea pigs the mouse virus by transmitting it in series and distinguishing (1) central paralytic forms, which are incurable, with lesion of the motor neurons; (2) peripheral paralytic forms, which are sometimes curable, since they affect only the neuromuscular synapsis; (3) nonparalytic forms with a febrile type (neutralization of the virus by the sick animal's plasma and not by the normal ones); (4) an apyretic nonparalytic type of great epidemiologic interest, since it might be a source for the transmission of the disease.

Dr. L. Arteta, head of the Necropsy Department of the Madrid General Hospital and Assistant Professor of the Faculty of Medicine, a pupil of the Cajal-Tello-De Castro trio, has made a deep study of pellagra. He has studied in great detail the tongues of pellagrous patients, microscopically and macroscopically, rigorously excluding possible causes of error, proving the existence of a noninflammatory (i. e. degenerative) segmentary neuritis with trophic alterations of the remaining components of the tongue. Basing his work on histology, he comes to the conclusion that glossitis is a disturbance consecutive to primitive alterations of the nervous system. Arteta proposes, to designate the absence of inflammatory manifestations and to honor the Spanish investigators who discovered pellagra, the use of the term "Casal's glossopathy."

Arteta also has described the technic of a new silver staining method which is particularly constant and applicable to large sections of organs of the nervous system preserved for a long time in solution of formaldehyde. Finally he has devised a technical modification of Ferry's method destined to make permanent the dryings with polychrome blue which so far have been used in the rapid diagnosis of pathologic tissues in surgical operations; he has achieved stabilization of the color, using a fixing solution of ammonium molybdate and a few devices of his own.

Correspondence

CARBOHYDRATE METABOLISM IN ULCER PATIENTS

To the Editor:—In their article "Gastric Operations" in The Journal, June 14, Zollinger and Hoerr describe a group of ulcer patients with postoperative symptoms which they attribute to a disturbance in blood sugar levels. One is led to believe that this disturbance is due to the altered gastrointestinal physiology caused by the surgery. These authors report that both hypoglycemic and hyperglycemic curves were observed in their patients. I studied sugar tolerance curves in a group of ulcer patients who had never undergone surgery and who were being treated medically in an outpatient department and in the ward. Practically every patient had an abnormal tolerance curve. The majority showed hypoglycemia, the remainder hyperglycemia. I also found similar abnormal curves in patients with typical ulcer symptoms but without signs of ulcer on x-ray examination. Both ulcer and pseudoulcer patients responded to a low carbohydrate diet aimed to overcome the abnormal blood sugar levels. The results of this study were published in a paper titled "The Pain Mechanism in Ulcer and Pseudoulcer Syndromes" (*Rev. Gastroenterol.* 7:485 [March-April] 1940). There was a definite correlation between the pain in ulcer and a fall in blood sugar. In hypoglycemic patients the pain coincided with a fall to absolute hypoglycemic levels. In patients with hyperglycemia the pain coincided with periods of sharp fall, not necessarily to hypoglycemic levels. In hyperglycemic patients the fall in blood sugar was sharp and to "relative hypoglycemia," a term used by several authors to explain typical hypoglycemic symptoms in hyperglycemic patients. The relief from pain which follows the ingestion of food in ulcer was correlated with a rise in blood sugar following the ingestion of food.

From my studies I concluded that the fundamental cause of ulcer and pseudoulcer symptoms was a disturbance in carbohydrate metabolism caused primarily by the ingestion of foods containing starch and sugar. The relief from symptoms such as, pain, flatulence, heartburn, nausea, weakness, faintness, headache and syncope, with a low carbohydrate diet, was attributed to the normal blood sugar levels that are obtained with such a diet. It is thus apparent that the disturbance in carbohydrate metabolism in ulcer patients is fundamental and is present in the patient who has not been operated on. Surgery may aggravate this disturbance. The beneficial effects that are observed with frequent feedings in these patients I have attributed to the stabilizing effect of such a regimen on blood sugar levels. Frequent feedings of milk and cream are especially beneficial, since such a regimen contains no starch and little sugar.

The diet employed by me ranged from 2,300 to 2,900 calories (carbohydrate, 114 to 124 Gm.; protein, 101 to 129 Gm.; fat, 161 to 212 Gm.). Aside from six thin soda crackers each day, there was no starch or sugar allowed. Recently I have eliminated the crackers from the diet. The carbohydrate allowed was ingested chiefly in the form of 5 and 10 per cent vegetable. Fruits were allowed rarely, and no fruit juices were allowed at all. In recent years several authors have stressed the beneficial effects of protein foods and protein hydrolysates in the treatment of ulcer. These authors give one the impression that the protein is chiefly responsible for the good results obtained. This could apply in patients with hypoproteinemia. However, most ulcer patients have no hypoproteinemia. The diet employed in my study had a high protein content. But I have attributed the good results mainly to the absence of starch and sugar. A diet which is high in protein and which contains ordinary amounts of starch and sugar will not prove beneficial. The starch and sugar must be eliminated.

MEDICOLEGAL ABSTRACTS

Selective Service Act: Physician Need Not Reemploy Discharged Attorney to Handle Collection Work.—The plaintiff filed an action against the defendant physician claiming that he had been denied the reinstatement and compensation to which the provisions of the Selective Service Act entitled him. The case was heard in district court D, Maryland.

The defendant physician specialized in the examination and treatment of the eye and the prescribing and furnishing of eye glasses to his patients. Most of his large professional practice was conducted on a credit basis, and in July 1942 he employed the plaintiff attorney to collect his regular and delinquent accounts, paying him a salary plus commission for such services. On July 1, 1943 the plaintiff was inducted into the armed forces. During the plaintiff's absence the defendant employed various persons and a collection agency to handle his collections but none of them were paid a salary; they all worked for a straight commission. The plaintiff was discharged in February 1945 and sought reinstatement with the defendant, who offered the plaintiff a permanent position as sole collector in the same territory in which he had worked before the war but solely on a commission basis. This the plaintiff refused, claiming that he was entitled to be reinstated to a position of "like pay," which, he argued, could be accomplished only by paying him a salary plus a commission.

It must be noted, said the court, that the act exempts the employer from making a reinstatement completely equivalent to the former job if "the employer's circumstances had so changed as to make it impossible or unreasonable to do so." We agree, continued the court, that some very clear reason must be given for the refusal on the part of the employer to give reinstatement to the returning veteran according to the express terms of the act. We also agree that "unreasonable" means more than "inconvenient" or "undesirable." The precise question for decision, continued the court, is this: Was the defendant justified in refusing to reinstate the plaintiff on the basis of compensation which plaintiff demands? In other words, has the defendant sustained the burden which rests on him of proving that "[his] circumstances have so changed" between the time when the plaintiff left the employment of the defendant and when he applied for reinstatement "as to make it impossible or unreasonable" for the defendant to restore the plaintiff to a position of "like pay"?

The testimony shows that in 1942 when the plaintiff entered the defendant's employment, the defendant had on his books more than $32,000 in outstanding accounts, representing 4,115 individual accounts. The corresponding figures for 1943 were $24,640 and 3,213 accounts; for 1944, $9,673 and 1,270 accounts; for 1945, $6,078 and only 707 accounts; and in February 1945, at the time when plaintiff sought reinstatement, $5,819, represented by 731 accounts. These figures stand uncontradicted and indicate a very substantial decline in defendant's professional work while plaintiff was in the service, which, defendant testified, was due very largely to the fact that, during the peak period of the war, he was called on to make an abnormal number of eye examinations for workers in local war plants, and that, as war production and the amount of war plant labor became greatly reduced when the war ended, these examinations fell off correspondingly. During October 1942, November 1942 and April 1943 the defendant expended in monthly commissions approximately $235. During the first six months after plaintiff's discharge, defendant expended an average per month of approximately $110, or less than half of the amount spent in the three months referred to. These figures clearly indicate that there is nothing padded, no misrepresentation, in defendant's position. His business showed a very material falling off, which doubtless justified retrenchment along several lines. Was he justified in adhering to this retrenchment in outlay for collecting accounts when the plaintiff sought restoration of his former position? We believe, said the court, that the defendant was so justified.

To decide otherwise would be tantamount to saying that, although there is no need to have a particular type of position in a given business nevertheless the act requires that it be set up again for the benefit of the ex-serviceman Here there is no question of competition or personality involved but merely the abolition of a salary arrangement long prior to the return of the plaintiff, because the defendant decided reasonably and honestly, as we believe owing to a very substantial reduction in the number of those whose eyes he examined that he no longer required the services of a salaried collector The court accordingly entered a judgment in favor of the defendant physician —*Myers v Barenburg, 68 F Supp 697 (1946)*

Medical Motion Pictures

FILM REVIEWS

Errors of Refraction Directed by William Alfred Mann M S M D and Emile George Nadeau B S M D Produced in 1941 by Northwestern University Medical School Photography by Mervin W LaRue 16 mm color silent 1,700 feet (one reel) Showing time fifty minutes Procurable by rental $4 or by purchase from Audio Visual Medical Education Department Northwestern University Medical School 303 East Chicago Avenue Chicago 11

The purpose of this film is to present the basic principles involved in the optical properties of lenses and the refractive errors of the eye The subjects included are simple refraction, prisms convex lenses various forms of convex lenses concave lenses cylindric lenses the normal eye the formation of an image accommodation presbyopia emmetropia myopia hyperopia myopia hyperopia and astigmatism

This film done entirely in animation begins with a series of colored perspective pictures showing the deflection of light by passage through glass in the form of rectangular blocks prisms, cylinders and other solid forms It shows the structure of the human eye and how an external object consisting of a pattern of points, becomes represented by an inverted pattern of point images on the retina Colored diagrams illustrating the meaning of 'diopter' serve to introduce a discussion of accommodation hyperopia myopia and presbyopia

The question arises whether the film teaches anything that could not be taught more accurately and at less expense by a book of black and white diagrams and a precise use of mathematical terms The film labors the simple and obvious and gets into difficulty as soon as it approaches even such simple concepts as that of the conoid of Sturm (misspelled Sturm in the film) More difficult concepts like that of the toric lens, the movements of images in the plane and concave mirrors used in retinoscopy, corresponding points and the horopter are the ones on which medical students need help It is evident that the difficulty of illustrating these ideas by a movie would be huge

The film would be useful early in a course in ophthalmology or in physiologic optics as a loose review of elementary facts, to give a glow of color, as it were, to the subject It is not sufficiently detailed to constitute a good introduction by itself, and since it does not undertake to illustrate anything whatever of an advanced nature it is not likely to prove useful in later work

Removal of Dermoid Cyst of the Orbit Prepared in 1942 by Rudolph Jaeger M D Jefferson Hospital Philadelphia 16 mm color silent 400 feet (one reel) Showing time sixteen minutes Procurable on loan from Author Jefferson Hospital 10th and Sansom streets Philadelphia 7

This short film is interesting and instructive Most of the photography is fairly good Occasionally the focus is not changed quickly enough for the manipulations involved The technic of the operation is good, but there is not much documentation There is no history of the patient no differential diagnosis and but little follow-up of the patient In this type of case ocular movements are of paramount importance and, although the pupils are equal in the film the patient is not asked to look in all directions, which would demonstrate normal ocular movements The actual removal of the tumor is not obvious to the onlooker The cosmetic result is good

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Throat Medication: Survey of Current Trends. N. D. Fabricant.—p. 502.

Patent Ductus Arteriosus and Cardiac Murmurs.—Levine and Geremia studied 37 surgically verified cases of patent ductus arteriosus, with especial attention to the auscultatory signs. Many patients showed a moderate diastolic murmur. The diastolic component was never louder than the systolic; occasionally it was of the same intensity but generally it was fainter. A peculiarity commonly observed was that the murmur appeared to become louder during the latter part of systole, enveloping the second heart sound and continuing with decreasing intensity during diastole. A palpable systolic thrill was present in 21 of 37 cases. This was maximum in the second and occasionally in the first left interspace. It was always systolic in time but occasionally continued well into diastole. In doubtful or puzzling cases catheterization of the heart will be necessary to establish an accurate preoperative diagnosis and avoid harmful surgery.

Clinical and Laboratory Features of Infectious Hepatitis.—Zimmerman and his associates studied 295 cases admitted to a general hospital in eastern France. On the day after entry the blood count, icterus index and urine examinations were performed. Blood icterus determinations and pigment studies of the urine were repeated at three day intervals throughout the hospital stay. Other laboratory studies were performed as indicated. Different disease patterns were differentiated depending on the presence or absence of jaundice, occurrence of relapses and severity. The incubation period was estimated to fall within the accepted three to six week range. Onset was categorized on the basis of the insidiousness or rapidity of the symptom evolution and presence or prominence of systemic and respiratory symptoms. Anorexia, dark urine, malaise, nausea and abdominal pain were the most common symptoms. Jaundice, tender hepatomegaly, adenopathy and occasional splenomegaly were the significant signs. Duration of signs and symptoms was rarely less than five weeks, and many patients had residual disease after eight weeks. Although no deaths occurred, there were 6 cases which showed a clinical picture said to herald a fatal outcome. Most complications were mild. Gingivitis, skin petechiae, melena, epistaxis and "liver spots" occurred. The typical hemogram revealed no anemia but a tendency to reversal of the lymphocyte-neutrophil ratio and slight increase in eosinophils. Elevated serum globulin is of diagnostic and prognostic significance. Patients with deep jaundice, bradycardia and itching had bile salts in the urine. Rest and a diet with high protein and low fat content are the most important factors in treatment.

Pharmacologic and Clinical Experiences with Benadryl.—McGavack and his associates observed 60 normal subjects and 242 patients in order to obtain pharmacologic data and evaluate the therapeutic range and the unpleasant side effects of benadryl. Benadryl is an alkamine ether with a powerful antihistamine action. This is indicated by its ability to suppress completely the dermal and gastric responses to histamine and to decrease capillary permeability. These effects are further demonstrated through the clinical relief afforded patients with diseases in which sudden and/or prolonged releases of excessive quantities of histamine play a pathogenic role. An atropine-like activity for benadryl is suggested by its effects on the eye when applied topically. The variations in blood pressure may simulate one phase of the action of atropine. Disturbances in the sensorium observed in some of the patients receiving the drug have suggested a scopolamine-like action. From the clinical point of view it can be said that benadryl is an exceedingly potent antihistamine and antispasmodic drug which lacks unpleasant cardiovascular and nervous side effects attendant on the use of sympathomimetic agents such as epinephrine, ephedrine and amphetamine. Toxic reactions, while common, rarely preclude its continued use.

Streptomycin in Peritonitis. H. A. Zintel.—p. 443.
Topical Use of Streptomycin in Wounds. E. L. Howes.—p. 449.
Present Status of Treatment for Influenzal Meningitis. Hattie E. Alexander and Grace Leidy.—p. 457.
*Treatment of Tularemia with Streptomycin. L. Foshay.—p. 467.
Treatment of Urinary Tract Infections with Streptomycin. W. L. Hewitt.—p. 474.
Streptomycin Therapy in Undulant Fever. G. H. Finch.—p. 485.
Toxicity of Streptomycin. W. McDermott.—p. 491.

Streptomycin in Tuberculosis.—Hinshaw and his associates administered streptomycin to more than 100 patients with tuberculosis of various types. Experience with this antibiotic agent proved that tuberculosis is amenable to antibacterial therapy. Streptomycin is predominantly bacteriostatic rather than bactericidal, and its therapeutic value is limited by the fact that after exposure to streptomycin for weeks or months strains of Mycobacterium tuberculosis which are resistant to the effects of the drug may be isolated. Hence streptomycin is of most value in conditions in which temporary suppression of the infection will enable the patient to gain the ascendancy over his disease, as in cases of hematogenic tuberculosis, including generalized miliary tuberculosis and tuberculous meningitis. For these conditions large doses (1 to 3 Gm. daily) must be given parenterally for several months. For meningitis intrathecal injections are imperative also during the early weeks of treatment. Exudative pulmonary disease, ulcerating lesions of the respiratory tract and tuberculous draining sinuses have responded to treatment with streptomycin. It has some place in the treatment of bilateral renal tuberculosis or tuberculosis of a solitary kidney. It is also used before and after thoracic surgery for pulmonary tuberculosis. Because of the potential toxicity, use of the drug may be contraindicated in conditions which will respond satisfactorily to the usual methods of treatment.

Streptomycin in Tularemia.—Foshay employed streptomycin in the treatment of patients of an average age of 36 years with tularemia. One patient died, giving a fatality rate of 2.7 per cent for the series. The time of onset of therapy ranged from the second to the one hundred and twenty-third day of disease, with the average on the twenty-second day. Streptomycin was administered by intramuscular injection every three hours, occasionally every four hours. A few dangerously ill patients received part of the total amount by continuous intravenous or subcutaneous drips. The periods of administration varied from two to seventeen days and the total dosage from 0.64 to 29.5 Gm. A duration of disease of less than two months and a therapy-to-recovery interval of considerably less than forty-six days are new low constants for tularemia. Four patients were desperately ill, exhibiting the highly febrile, incontinent, stuporous, typhoid state. Transitions from this to one of cheerful competence with sustained progressive improvement were effected within seventy-two hours. In 10 patients with pneumonia and pulmonary exudates streptomycin therapy apparently effected a considerable reduction in the resolution time and, on the average, the less the interval between detection of pneumonia and institution of therapy the shorter was the period of repair. Although the experience is too small to permit formulation of an optimal dosage, no evidence has yet appeared that either (1) 0.5 Gm. per day for two days followed by 0.25 Gm. per day for four days or (2) 0.5 Gm. per day for six days is not adequate dosage for the case of usual severity, with or without tularemic pneumonia.

Rh Antibodies in Rh-Negative Mothers.—Howard and her associates present an analysis of laboratory observations in 179 pregnant Rh-negative women. The study was undertaken in order to determine the relationships which might exist between the serologic data observed in the mothers and the clinical conditions found in the infants born to them, with the ultimate purpose of presenting the obstetrician with an antepartum interpretation of the significance of the laboratory findings in Rh-negative patients. The data were classified according to the Rh characteristic and the clinical conditions of the infant: group I, normal Rh-negative infants; group II, normal Rh-positive infants; group III, Rh-positive infants with subclinical hemolytic disease of the newborn, and group IV, Rh-positive infants with frank hemolytic disease of the newborn. There were 61 women in group I, 78 in group II, 17 in group III and 20 in group IV. In general, no patient demonstrating a high antepartum titer of either antibody, especially if their presence was detected early in pregnancy, was delivered of a clinically normal Rh-positive infant. A comparison of the occurrence of Rh agglutinin and blocking antibodies indicates that no definite cause and effect relationship between them can be inferred. There appears to be an apparent reciprocity between the titer trends of these two antibodies the significance of which is not entirely clear. The Rh agglutinin appears to be demonstrable in the maternal serum by the twentieth week ante partum. The blocking antibody follows the appearance of the Rh agglutinin and may not be present in demonstrable amounts earlier than about the tenth week antepartum. The hypothesis is suggested that blocking antibody may be produced not as a defense for the mother as is Rh agglutinin but as a protection for the erythrocytes of the fetus.

Selective Cytology Smear for Diagnosis of Cancer.—According to Ayre the original technic for the diagnosis of uterine cancer by the vaginal smear method was arduous and time consuming in the microscopic search for the specifically malignant cells sometimes obscured by the cellular desquamata, leukocytes and blood. Ayre describes a selective cytology technic which was developed in order to obtain evidence of cancer growth in the cells which become earliest involved in cervical cancer. The squamous cells encircling the tiny cervical opening at the squamocolumnar junction constitute a key point of origin for cancer. The spatula test offers a technic providing "surface biopsy" information of these cells prior to their desquamation. By study of these cells, morphologic changes have been identified believed to constitute a precancer cell complex. Many of these so-called precancer cases have shown clinically normal cervices, but the biopsies have verified the suspicious nature of the lesions. The selective cytology technic has been found to be more accurate as an indicator of endogenous estrogen by cornification counts in smears from the cervix and vagina in cancer cases. The previous aspiration method failed to reveal the true cornification level because of excessive amounts of blood and leukocytes obscuring the picture. Through early diagnosis of cancer by routine cytology tests, death from cancer of the cervix should become highly preventable.

Time of Ovulation.—The material comprising this report by Brewer and Jones was obtained from 100 women who were in active menstrual life and who had normal menstrual cycles. The material consists of surgical specimens of the ovary, ovaries or resected portions of ovaries and endometrium. The 100 patients were operated on on various days of the cycle. Days 3 and 27 were the only two days on which no patient was operated on. Diagrams with numbered and unnumbered blocks indicate day of operation, day of ovulation and estimated age of corpus luteum. Fifty-four of the 100 patients had ovulated during the present cycle studied. The range of time of ovulation is from the eighth through the nineteenth day of the cycle. The greatest number ovulated on days 12, 13, 14 and 15, with the highest peak on day 14. The author also reviews observations on ovulation made by other investigators and says that the consistency of the various reports, many of which are based on determination of age of corpora lutea, indicate that it is possible to estimate the age of corpora lutea with reasonable accuracy by histologic and cytologic methods.

Universal Serologic Reactivity with Lipid Antigens.—Kahn presents data which show that lipid antigen and serum employed in tests for syphilis can be so treated technically as to elicit positive precipitation reactions in most nonsyphilitic per-

Sulfonamide Psoriasiform Dermatitis.—Philpott observed a cutaneous eruption which he thinks is due to sulfonamides. It is a type of psoriasiform dermatitis exhibiting many of the essential features of psoriasis. He reports 3 cases which illustrate some of the clinical features of this condition. All 3 patients were women. In each the eruption followed relatively soon after she had taken a sulfonamide drug; in each the appearance of the eruption warranted a clinical diagnosis of psoriasis, and in 2 of the 3 the microscopic diagnosis was consistent with that of psoriasis. None of the 3 had a suggestive hereditary history; none had previous disturbances of the skin. The duration of the eruption in 1 was four months, and the skin has been clear six months. In another the lesions were present four months and cleared from the body but remained in the scalp for fifteen months and then reappeared and have been present ever since. The third still has lesions and has had them continuously for twenty-one months. This experience points to infective processes as an inciting factor of initial attacks of psoriasis; apparently the sulfonamide compounds may act similarly. Holman suggests the possibility of the existence of psoriatic patients in whom the disease remains below the threshold of the eruptive phase until some potent excitant such as a sulfonamide drug precipitates an eruptive reaction.

Cerebral Anoxia from High Altitude Asphyxiation.—Titrud and Haymaker report 3 cases of anoxic anoxia occurring in aviators while engaged in combat. In 2 cases the anoxia proved fatal in forty hours and three weeks, respectively, and the third patient was observed for a period of three weeks and then was transferred. In the first, the accident occurred at an elevation of "more than 20,000 feet," the patient being found unconscious five minutes after completion of a bomb run, at which time resuscitation was commenced. The second patient was exposed to an atmosphere at 24,000 feet for approximately ten minutes. In the third, it was at 27,000 feet that the oxygen tank of the plane was shot away, necessitating a rapid descent to 7,000 feet, during which time no effort could be made to revive the patient. In the case of forty hours' duration necrosis of ganglion cells was observed in the third to sixth laminas of the cerebral cortex, the striatum, the cerebellum, Sommer's sector of the hippocampus and the anterior horns of the spinal cord, mostly focal in character, and degeneration of myelin in the internal capsule. Also observed were early proliferation of the fixed tissue cells of the leptomeninges and vascular adventitia and mild exudation of lymphocytes and neutrophils into the meshes of the arachnoid, the perivascular spaces and, to a limited extent, the parenchyma of the brain. In the case of three weeks' duration the changes were of virtually the same location except that the cerebral white matter, brain stem and spinal cord were relatively spared. The damage in these cases of sudden and severe anoxic anoxia is strikingly similar to that observed in some of the other forms of anoxia.

Japanese B Encephalitis.—Lewis and his associates review the clinical characteristics of Japanese B encephalitis as observed in an outbreak in the civilian population of Okinawa Shima. They present an analysis of symptoms and physical signs in 65 patients and reports of 7 cases illustrating variations in the course and outcome of the disease. The disease was most common among children, resulting in a mortality of 20 per cent, and caused permanent disorder of the nervous system in at least one fifth of the patients. The manifestations were characteristic of a diffuse encephalomyelitis and resembled those of other neurotropic virus infections. The gross and microscopic lesions of the nervous system are compared with those of other virus encephalitides.

Medulloblastoma of Cerebellum, with Survival for Seventeen Years.—According to Penfield and Feindel, medulloblastoma of the cerebellum seems invariably fatal in spite of the fact that it is temporarily sensitive to roentgen therapy. Reports in the literature have pointed out the tendency to longer survival from this tumor in adults. In the case reported a medulloblastoma of the cerebellum made its appearance when the patient was 22 years of age. There was recurrence of symptoms after nine years and again after sixteen years. In the first (and probably the second) instance the recurrence was at a distance from the cerebellum, and in each the result of roentgen therapy was initially satisfactory. Although the histologic appearance suggested a high degree of malignancy, there was survival for seventeen years.

Plantar Corns.—Vasko says that plantar corns are frequently misdiagnosed as plantar calluses and sometimes as plantar warts. Plantar calluses and plantar corns may look alike, but the former are not tender while the corns are exquisitely so. The surest way to discover whether the callus conceals a corn or not is to pare off the top. Should a corn be present, one will encounter a small hard kernel like a rice body. A plantar wart is usually not surrounded by callus. Also a wart has the appearance of the cross section of a nerve and is usually moist and soft, whereas the corn is dry and hard. In the treatment advocated by Vasko the corns are trimmed of excess callus and the hard kernel in the center removed with a small, blunt, round ended knife. The skin underlying this kernel was always pink and rather tender. A subcutaneous injection of 1 cc. of 1 per cent procaine was then made into the base, and it was noticed that considerable pressure had to be used to force the procaine in. Apparently the skin on which the base of the corn rested was adherent to the fibrous element of the subcutaneous fat. The injection was quite uncomfortable for a moment, but after the ballooning of the tissue was accomplished the pain ceased. Painless walking was possible almost at once. In a few cases the relief was permanent, but in the majority some discomfort returned within a few days. The latter group received additional injections. To avoid disappointment in the treatment of verrucae and simple calluses, it is recommended that this treatment be used only on plantar corns.

Giant Hypertrophic Gastritis.—Six cases of giant hypertrophic gastritis, 2 with superimposed hyperplastic polyp formation, are described by Maimon and his co-workers. The difficulty in differentiating this condition from neoplasm is evident from the fact that all 6 were subjected to operation. The symptomatology is indefinite. Anatomically, roentgenologically and gastroscopically the resemblance of the gastric folds to the convolutions of the brain is striking and is perhaps the most salient feature. Microscopic examination reveals redundancy of the mucosa and hypertrophy of the glandular structures, with cyst formations and metaplasia to the intestinal type of epithelium. The pepsinogen and acid forming cells are replaced by the more primitive type. Fibroplasia with increase of connective tissue and edema were prominent features. In 2 cases redundancy was outstanding, while in 2 others hyperplasia and increased thickness of the mucosa were remarkable. Multiple polyps developed in 2 cases.

Protein Hydrolysate Therapy for Peptic Ulcer.—Hodges evaluates the effectiveness of the oral administration of a protein hydrolysate in the treatment of chronic peptic ulcer and makes observations pertaining to nutrition and metabolism in human subjects whose sole source of dietary nitrogen was predigested protein. Twenty-six patients have been selected for this study. Twenty-four had received adequate conventional dietary therapy previously without significant improvement or had suffered a recurrence of symptoms while adhering to such a program. The patients were treated with a protein hydrolysate-carbohydrate mixture for from two to three weeks. In the majority this treatment appeared more efficacious than a conventional dietary program in producing a remission, but the frequency of relapses was not diminished. Three patients failed to respond satisfactorily, one of these suffering a serious gastrointestinal hemorrhage in the midst of therapy. A gain in weight was the rule. A rise in blood urea nitrogen was seen in most of the patients, but the serum protein and hemoglobin changes were inconsistent. The degree of gastric acidity after treatment tended to be reduced. Individual feedings of this mixture completely neutralized free gastric acid for an average of seventy minutes. The beneficial effects of the protein hydrolysate are ascribed to its buffering action and to the high nitrogen intake. It is believed that the protein hydrolysate may become a useful adjunct to the medical management of peptic ulcer but will not prove to be a panacea.

Bacterial Resistance to Streptomycin.—Experiments made by Price and his associates revealed that different species of bacteria and different strains of the same species vary greatly in their in vitro resistance to streptomycin and streptothricin. Resistance of organisms to streptomycin was more readily induced than to streptothricin, and to a greater degree. Streptomycin-induced resistance of Eberthella typhosa is accompanied with changes in morphology. In order to make comparative studies of the sensitivities of organisms to streptomycin it is imperative to employ a broth of uniform hydrogen ion concentration containing the same constituents. Furthermore, it is imperative that in testing an organism for sensitivity to streptomycin it be tested in the same batch of broth in which its original sensitivity was determined. It would be well for laboratories to maintain a reference standard medium against which all subsequent batches of medium could be tested with an organism of previously established sensitivity. When rats are fed on a diet containing streptomycin there appear in a relatively short time in the feces of these animals large numbers of microorganisms which are extremely resistant to this antibiotic.

Paroxysmal Hypertension.—Bauer and Belt report paroxysmal diffuse swelling of the thyroid accompanying and simultaneous with paroxysmal attacks of hypertension in a woman aged 47. The sudden swelling of the thyroid gland added to the usual signs and symptoms characteristic of the adrenal sympathetic syndrome reached its peak and faded away concurrently with the rise and fall of blood pressure in each hypertensive attack. There were extremely rapid and excessive variations in blood pressure, which usually are not associated with the syndrome. A tentative diagnosis of chromaffin tumor was made and corroborated by the finding that paroxysmal hyperglycemia accompanied the attacks. The diagnosis was established when the supposed tumor was visualized in the x-ray plate by perirenal insufflation A cure was affected by the surgical removal of the tumor under spinal anesthesia Microscopic examination of the specimen revealed a cystic pheochromocytoma of the adrenal gland

Action of Streptomycin on Type b Hemophilus Influenzae.—Alexander and Leidy found that of 14 patients treated with streptomycin alone 10 recovered promptly; in 3 of the 4 remaining cases failure was proved to be due to emergence of resistance of the organisms to streptomycin The rapid development of resistance to 1,000 units of streptomycin per cubic centimeter during treatment argues against metabolic adaptation of the bacteria Study of large samples of initial bacterial populations shows resistant members in all ten strains examined. The proportion of resistant members is not significantly higher before treatment in patients who do poorly than in those who respond promptly The results indicate that emergence of resistance is the result of a selective process, after elimination of sensitive members the very few resistant ones, apparently present in all strains, make up most or all of the population in the cultures taken after commencement of treatment. The survival of organisms which can grow in high concentrations of streptomycin, either in patients or in vitro, is influenced more by the size of the bacterial population than by any other known factor Since the bacterial population is relatively small in patients with mild or moderately severe infections, the likelihood of a significant number of highly resistant members being present is remote

Antibodies of Lymphogranuloma Venereum.—Wall studied the development of complement fixing antibodies in mice following infection with the virus of lymphogranuloma venereum. Antibody was always demonstrable at the end of two weeks after inoculation A peak in titer was reached three to five weeks after infection A high titer persisted throughout the eighteen week period of observation Virus could be recovered from the brains of the animals at any time after the appearance of signs of illness and throughout the period of recovery The sulfonamides are effective in the treatment of lymphogranuloma venereum, but animals treated with sulfonamides from the time of inoculation for a period of several weeks gave negative tests for antibodies at the end of this time In mice treated after the infection had been established, titers of antibody were lower than in control animals and a relationship was found between the end titer and the duration of therapy. When therapy was continued for several weeks, the antibodies disappeared completely Virus could still be recovered from the tissues of these animals, but the ease with which it was isolated depended on the program of chemotherapy

Serologic Response in Murine Typhus.—The studies reported by Nelson were undertaken primarily to investigate the course of antibody development in patients with murine typhus by comparing the results of the Weil-Felix test with the specific rickettsial agglutination and complement fixation reactions It was hoped that in this way it might be possible to evaluate more clearly the relative usefulness of the murine rickettsial agglutination and complement fixation tests in the early diagnosis of the disease Multiple samples of blood serum were collected over a period of several weeks from patients with clinical evidence of typhus infection. Almost all these patients were residents of communities in the Southeasten United States where murine typhus is endemic The serologic response in 22 cases of murine typhus has shown that the Weil-Felix and rickettsial agglutination reactions usually become positive earlier than the rickettsial complement fixation test in this disease As far as the detection of murine typhus in its acute stages in man is concerned, the relatively simple rickettsial slide agglutination test is fully as effective as the more elaborate complement fixation reaction
